Midterm evaluations

- **Thank you for doing midterm evaluations!**
- **First time not everyone thought I was going too fast**
  - Some people didn't like Q&A
  - But this is useful for me to gauge if people are following
  - In the past, have been asked to wait longer in Q&A
- **Slides that are skipped over will not be on exam**
- **People wanted handouts to take notes on**
  - I don't want to give out answers to Q&A
  - But want answers on web afterwards for you to review
  - Can try handouts with answer overlays removed

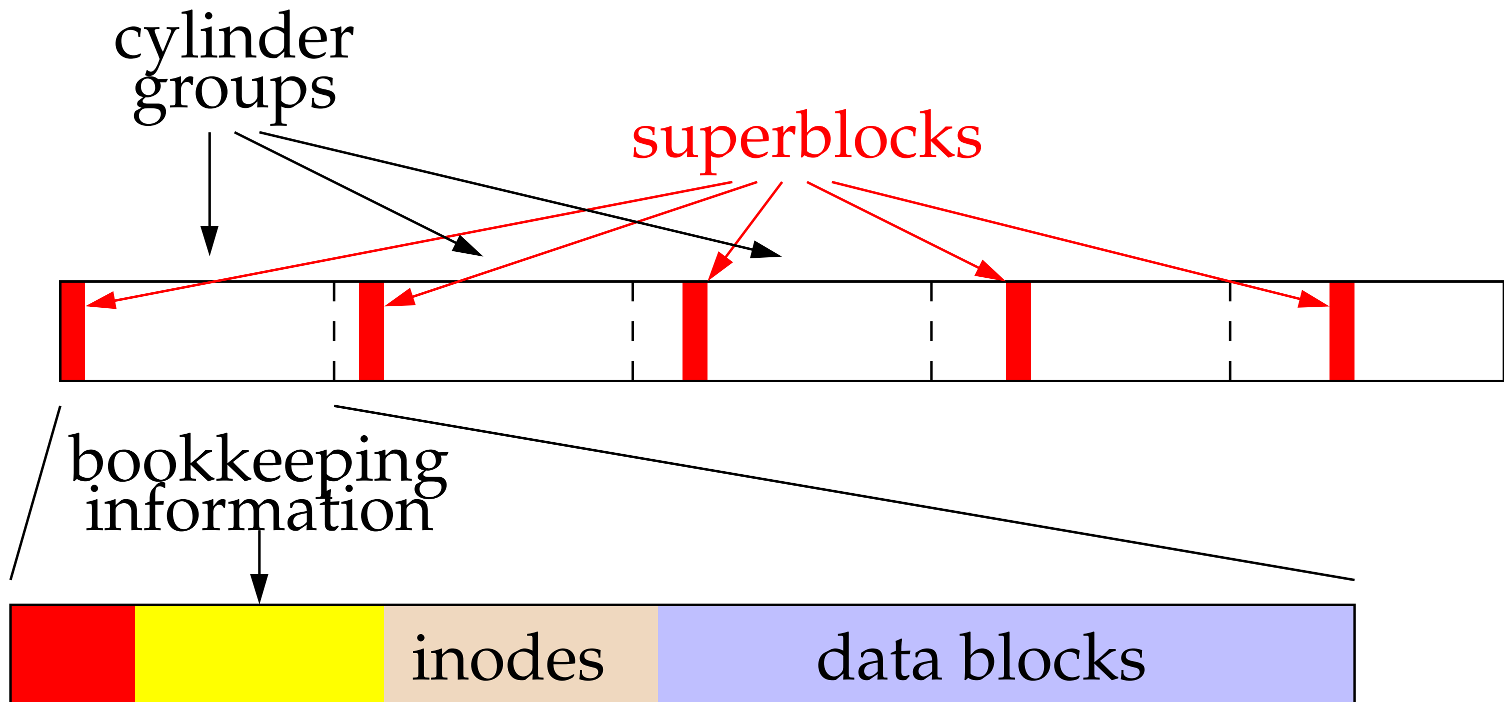
Review: FFS background

- **1980s improvement to original Unix FS, which had:**
  - 512-byte blocks
  - Free blocks in linked list
  - All inodes at beginning of disk
  - Low throughput: 512 bytes per average seek time
- **Unix FS performance problems:**
  - Transfers only 512 bytes per disk access
  - Eventually random allocation → 512 bytes / disk seek
  - Inodes far from directory and file data
  - Within directory, inodes far from each other
- **Also had some usability problems:**
  - 14-character file names a pain
  - Can't atomically update file in crash-proof way

Review: FFS [McKusic] basics

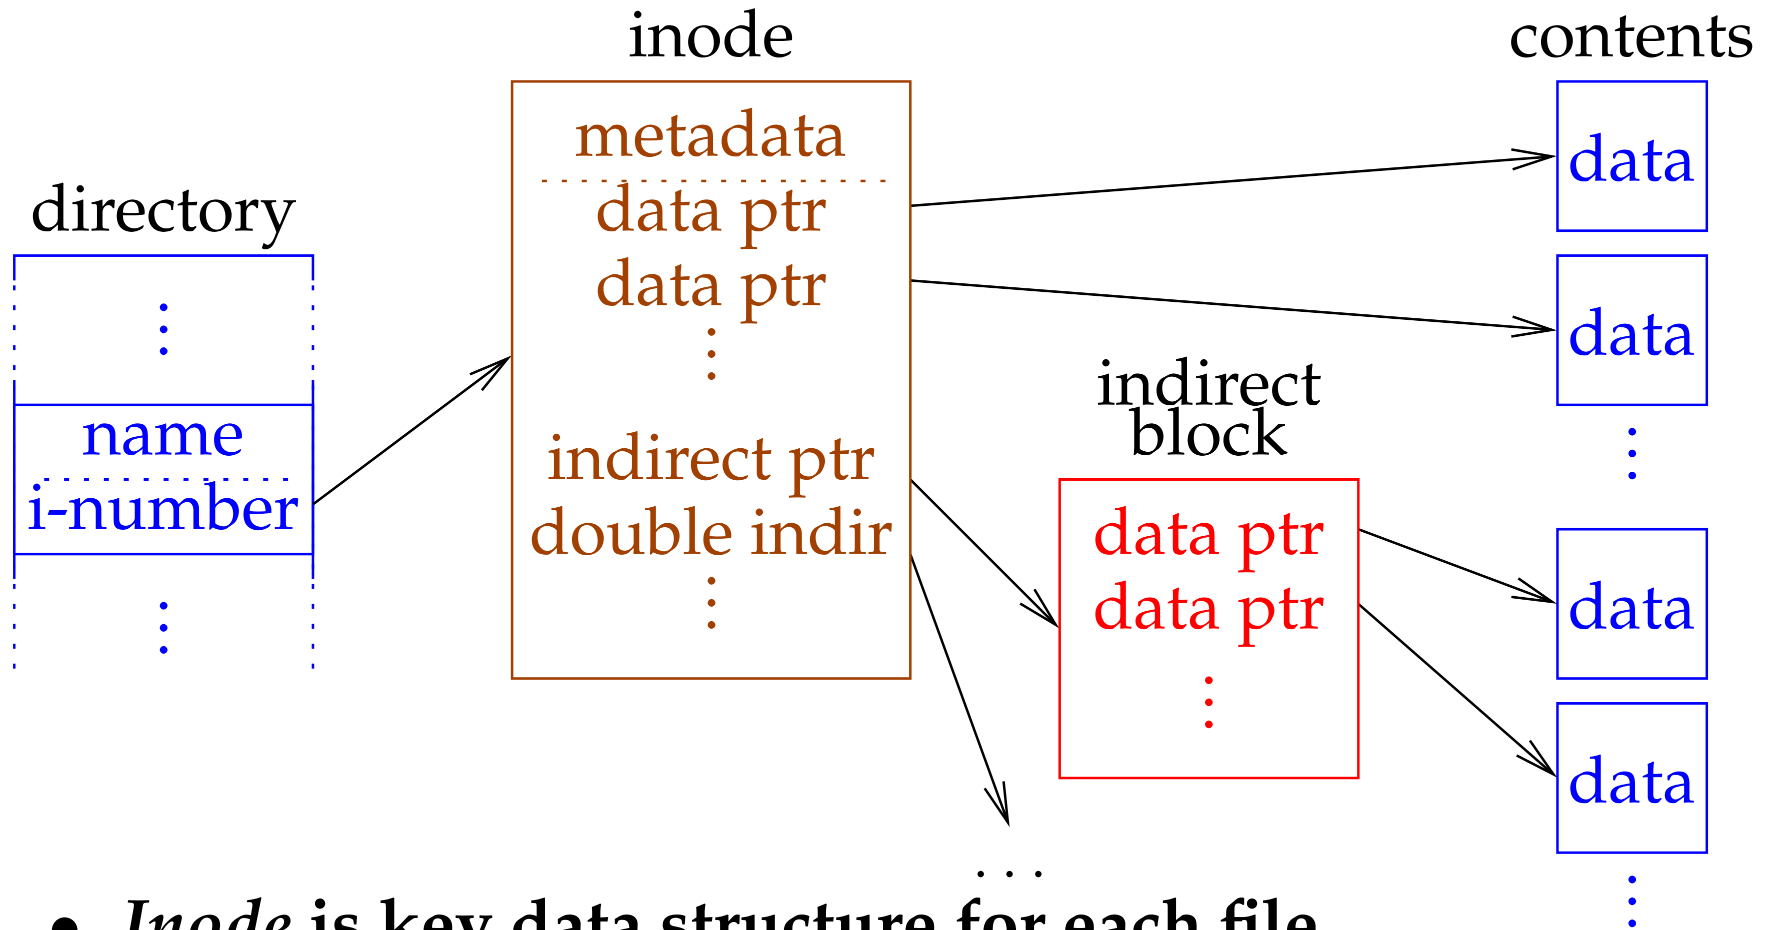
- **Change block size to at least 4K**
  - To avoid wasting space, use "fragments" for ends of files
- **Cylinder groups spread inodes around disk**
- **Bitmaps replace free list**
- **FS reserves space to improve allocation**
  - Tunable parameter, default 10%
  - Only superuser can use space when over 90% full
- **Usability improvements:**
  - File names up to 255 characters
  - Atomic *rename* system call
  - Symbolic links assign one file name to another

FFS disk layout



- **Each cylinder group has its own:**
  - Superblock
  - Bookkeeping information
  - Set of inodes
  - Data/directory blocks

Basic FFS data structures



- *Inode* **is key data structure for each file**
  - Has permissions and access/modification/inode-change times
  - Has *link count* (# directories containing file); file deleted when 0
  - Points to data blocks of file (and indirect blocks)
- **By convention, inode #2 always root directory**

FFS superblock

- **Superblock contains file system parameters**
  - Disk characteristics, block size, CG info
  - Information necessary to get inode given i-number
- **Replicated once per cylinder group**
  - At shifting offsets, so as to span multiple platters
  - Contains magic number to find replicas if 1st superblock dies
- **Contains non-replicated "summary info"**
  - # blocks, fragments, inodes, directories in FS
  - Flag stating if FS was cleanly unmounted

Cylinder groups

- **Groups related inodes and their data**
- **Contains a number of inodes (set when FS created)**
  - Default one inode per 2K data
- **Contains file and directory blocks**
- **Contains bookkeeping information**
  - Block map – bit map of available fragments
  - Summary info within CG – # free inodes, blocks/frags, files, directories
  - # free blocks by rotational position (8 positions)
    [In 1980s, disks weren't commonly zoned, so this was reasonable]

Inode allocation

- **Allocate inodes in same CG as directory if possible**
- **New directories put in new cylinder groups**
  - Consider CGs with greater than average # free inodes
  - Chose CG with smallest # directories
- **Within CG, inodes allocated randomly (next free)**
  - Would like related inodes as close as possible
  - OK, because one CG doesn't have that many inodes

Fragment allocation

- **Allocate space when user writes beyond end of file**
- **Want last block to be a fragment if not full-size**
  - If already a fragment, may contain space for write – done
  - Else, must deallocate any existing fragment, allocate new
- **If no appropriate free fragments, break full block**
- **Problem: Slow for many small writes**
  - (Partial) soution: new `stat` struct field `st_blksize`
  - Tells applications file system block size
  - stdio library can buffer this much data

Block allocation

- **Try to optimize for sequential access**
  - If available, use rotationally close block in same cylinder
  - Otherwise, use block in same CG
  - If CG totally full, find other CG with quadratic hashing
  - Otherwise, search all CGs for some free space
- **Problem: Don't want one file filling up whole CG**
  - Otherwise other inodes will have data far away
- **Solution: Break big files over many CGs**
  - But large extents in each CGs, so sequential access doesn't require many seeks

Directories

- **Inodes like files, but with different type bits**
- **Contents considered as 512-byte *chunks***
- **Each chunk has `direct` structure(s) with:**
  - 32-bit inumber
  - 16-bit size of directory entry
  - 8-bit file type (NEW)
  - 8-bit length of file name
- **Coalesce when deleting**
  - If first `direct` in chunk deleted, set inumber = 0
- **Periodically compact directory chunks**

Updating FFS for the 90s

- **No longer want to assume rotational delay**
  - With disk caches, want data contiguously allocated
- **Solution: Cluster writes**
  - FS delays writing a block back to get more blocks
  - Accumulates blocks into 64K clusters, written at once
- **Allocation of clusters similar to fragments/blocks**
  - Summary info
  - Cluster map has one bit for each 64K if all free
- **Also read in 64K chunks when doing read ahead**

Fixing corruption – fsck

- **Must run FS check (fsck) program after crash**
- **Summary info usually bad after crash**
  - Scan to check free block map, block/inode counts
- **System may have corrupt inodes (not simple crash)**
  - Bad block numbers, cross-allocation, etc.
  - Do sanity check, clear inodes with garbage
- **Fields in inodes may be wrong**
  - Count number of directory entries to verify link count, if no entries but count $\neq 0$, move to `lost+found`
  - Make sure size and used data counts match blocks
- **Directories may be bad**
  - Holes illegal, `.` and `..` must be valid, ...
  - All directories must be reachable

Crash recovery permeates FS code

- **Have to ensure fsck can recover file system**
- **Example: Suppose all data written asynchronously**
- **Delete/truncate a file, append to other file, crash**
  - New file may reuse block from old
  - Old inode may not be updated
  - Cross-allocation!
  - Often inode with older mtime wrong, but can't be sure
- **Append to file, allocate indirect block, crash**
  - Inode points to indirect block
  - But indirect block may contain garbage

Ordering of updates

- **Must be careful about order of updates**
  - Write new inode to disk before directory entry
  - Remove directory name before deallocating inode
  - Write cleared inode to disk before updating CG free map
- **Solution: Many metadata updates syncrhonous**
  - Of course, this hurts performance
  - E.g., untar much slower than disk b/w
- **Note: Cannot update buffers on the disk queue**
  - E.g., say you make two updates to same directory block
  - But crash recovery requires first to be synchronous
  - Must wait for first write to complete before doing second

Performance vs. consistency

- **FFS crash recoverability comes at *huge* cost**
  - Makes tasks such as untar easily 10-20 times slower
  - All because you *might* lose power or reboot at any time
- **Even while slowing ordinary usage, recovery slow**
  - If fsck takes one minute, then disks get $10\times$ bigger …
- **One solution: battery-backed RAM**
  - Expensive (requires specialized hardware)
  - Often don't learn battery has died until too late
  - A pain if computer dies (can't just move disk)
  - If OS bug causes crash, RAM might be garbage
- **Better solution: Advanced file system techniques**
  - Topic of rest of lecture

First attempt: Ordered updates

- **Must follow three rules in ordering updates:**
  1. Never write pointer before initializing the structure it points to
  2. Never reuse a resource before nullifying all pointers to it
  3. Never clear last pointer to live resource before setting new one
- **If you do this, file system will be recoverable**
- **Moreover, can recover quickly**
  - Might leak free disk space, but otherwise correct
  - So start running after reboot, scavenge for space in background
- **How to achieve?**
  - Keep a partial order on buffered blocks

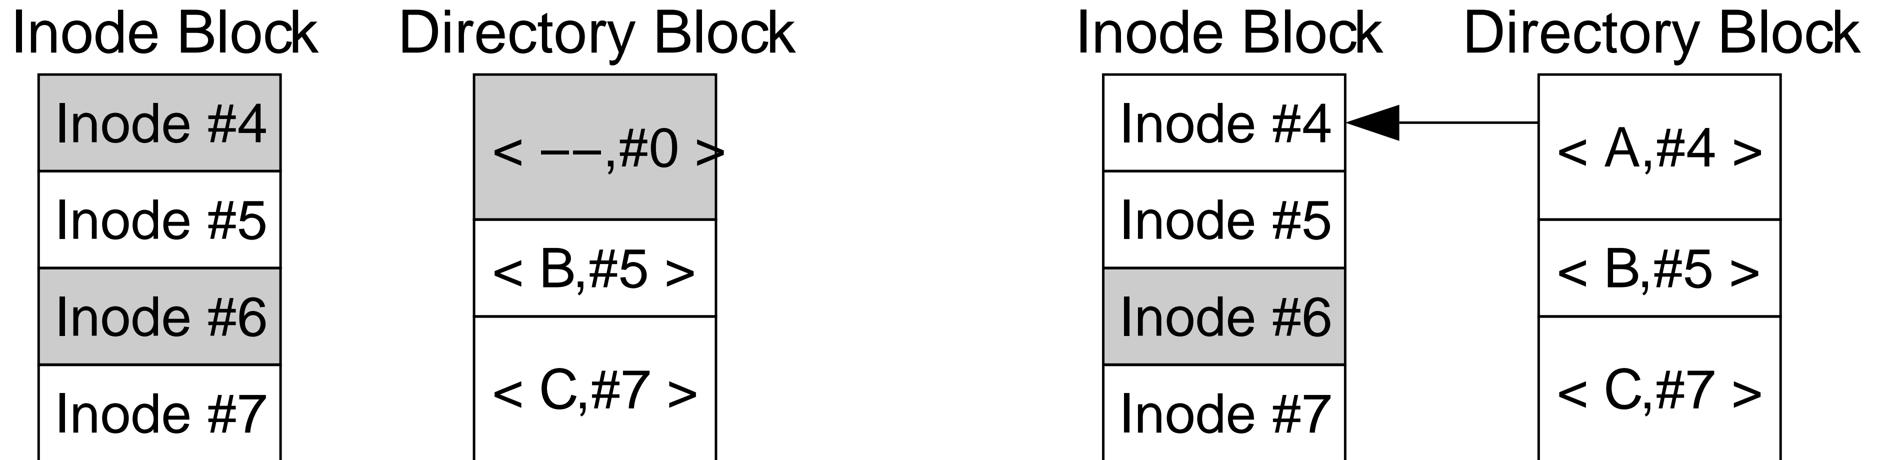
Ordered updates (continued)

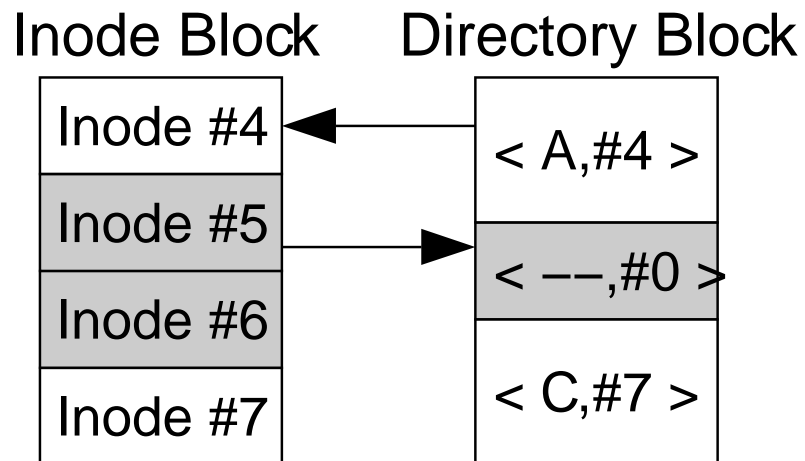
- **Example: Create file A**
  - Block X contains an inode
  - Block Y contains a directory block
  - Create file A in inode block X, dir block Y
- **We say $Y \rightarrow X$ meaning X must be written before Y**
- **Can delay both writes, so long as order preserved**
  - Say you create a second file B in blocks X and Y
  - Only have to write each out once for both creates

Problem: Cyclic dependencies

- **Suppose you create file *A*, unlink file *B***
  - Both files in same directory block & inode block
- **Can't write directory until inode *A* initialized**
  - Otherwise, after crash directory will point to bogus inode
  - Worse yet, same inode # might be re-allocated
  - So could end up with file name *A* being an unrelated file
- **Can't write inode block until dir entry *B* cleared**
  - Otherwise, *B* could end up with too small a link count
  - File could be deleted while links to it still exist
- **Otherwise, fsck has to be very slow**
  - Check every directory entry and inode link count

Cyclic dependencies illustrated





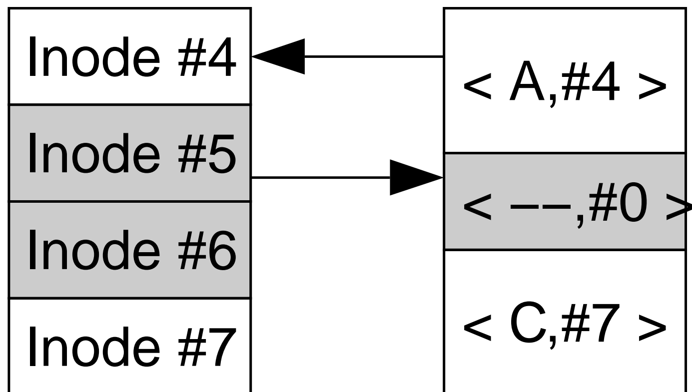
More problems

- **Crash might occur between ordered but related writes**
  - E.g., summary information wrong after block freed
- **Block aging**
  - Block that always has dependency will never get written back
- **Solution: “Soft updates” [Ganger]**
  - Write blocks in any order
  - But keep track of dependencies
  - When writing a block, temporarily roll back any changes you can’t yet commit to disk

Breaking dependencies w. rollback

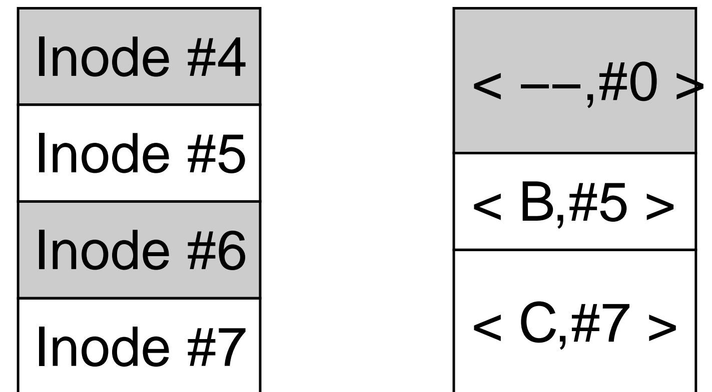
Main Memory

Inode Block Directory Block



Disk

Inode Block Directory Block



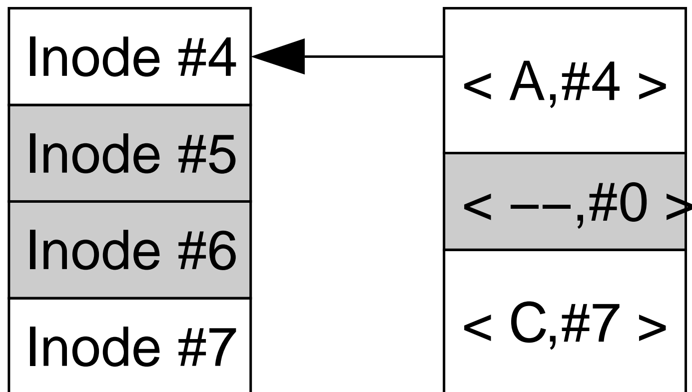
(a) After Metadata Updates

- **Now say we decide to write directory block…**

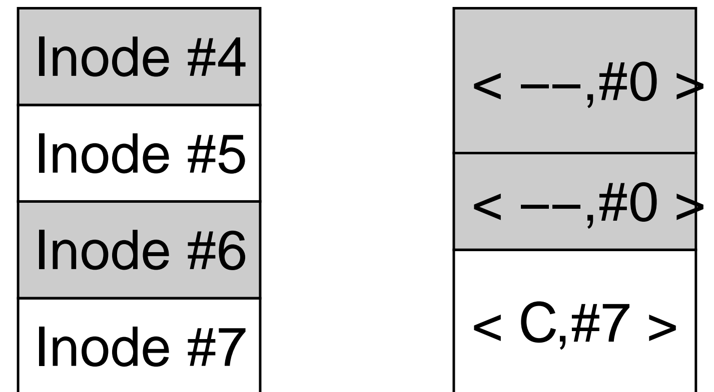
Breaking dependencies w. rollback

Main Memory | Disk

Inode Block | Directory Block



Inode Block | Directory Block



(b) Safe Version of Directory Block Written

- **Note: Directory block still dirty**
- **But now inode block has no dependencies**
- **Say we write inode block out…**

Breaking dependencies w. rollback

Main Memory		Disk	
Inode Block	Directory Block	Inode Block	Directory Block
Inode #4	< A,#4 >	Inode #4	< −−,#0 >
Inode #5	< −−,#0 >	Inode #5	< −−,#0 >
Inode #6	< C,#7 >	Inode #6	< C,#7 >
Inode #7		Inode #7	

(c) Inode Block Written

- **Now inode block clean (same in memory as on disk)**
- **But have to write directory block a second time…**

Breaking dependencies w. rollback

Main Memory

Inode Block

Inode #4
Inode #5
Inode #6
Inode #7

Directory Block

< A,#4 >
< −−,#0 >
< C,#7 >

Disk

Inode Block

Inode #4
Inode #5
Inode #6
Inode #7

Directory Block

< A,#4 >
< −−,#0 >
< C,#7 >

(d) Directory Block Written

- **All data stably on disk**

Soft updates

- **Structure for each updated field or pointer, contains:**
  - old value
  - new value
  - list of updates on which this update depends (*dependees*)
- **Can write blocks in any order**
  - But must temporarily undo updates with pending dependencies
  - Must lock rolled-back version so applications don't see it
  - Choose ordering based on disk arm scheduling
- **Some dependencies better handled by postponing in-memory updates**
  - E.g., Just mark block as free in bitmap after pointer cleared

Simple example

- **Create zero-length file** A
- **Depender: Directory entry for** A
  - Can't be written untill dependees on disk
- **Dependees:**
  - Inode – must be initialized before dir entry written
  - Bitmap – must mark inode allocated before dir entry written
- **Old value: empty directory entry**
- **New value:** $\langle$filename A, inode $\#\rangle$

Operations requiring soft updates (1)

1. **Block allocation**
   - Must write the disk block, the free map, & a pointer
   - Disk block & free map must be written before pointer
   - Use Undo/redo on pointer (& possibly file size)
2. **Block deallocation**
   - Must write the cleared pointer & free map
   - Just update free map after pointer written to disk
   - Or just immediately update free map if pointer not on disk

- **Say you quickly append block to file then truncate**
  - You will know pointer to block not written because of the allocated dependency structure
  - So both operations together require do disk I/O

Operations requiring soft updates (2)

3. **Link addition (see simple example)**
   - Must write the directory entry, inode, & free map (if new inode)
   - Inode and free map must be written before dir entry
   - Use undo/redo on i# in dir entry (ignore entries w. i# 0)
4. **Link removal**
   - Must write directory entry, inode & free map (if nlinks==0)
   - Must decrement nlinks only after pointer cleared
   - Clear directory entry immediately
   - Decrement in-memory nlinks once pointer written
   - If directory entry was never written, decrement immediately (again will know by presence of dependency structure)

- **Note: Quick create/delete requires no disk I/O**

Soft update issues

- ***fsync* – sycall to flush file changes to disk**
  - Must also flush directory entries, parent directories, etc.
- ***unmount* – flush all changes to disk on shutdown**
  - Some buffers must be flushed multiple times to get clean
- **Deleting large directory trees frighteningly fast**
  - *unlink* syscall returns even if inode/indir block not cached!
  - Dependencies allocated faster than blocks written
  - Cap # dependencies allocated to avoid exhausting memory
- **Useless write-backs**
  - Syncer flushes dirty buffers to disk every 30 seconds
  - Writing all at once means many dependencies unsatisfied
  - Fix syncer to write blocks one at a time
  - Fix LRU buffer eviction to know about dependencies

Soft updates fsck

- **Split into foreground and background parts**
- **foreground must be done before remounting FS**
  - Need to make sure per-cylinder summary info makes sense
  - Recompute free block/inode counts from bitmaps – very fast
  - Will leave FS consistent, but might leak disk space
- **Background does traditional fsck operations**
  - Can do in background after mounting to recuperate free space
  - Must be done in forground after a media failure
- **Difference from traditional FFS fsck:**
  - May have many, many inodes with non-zero link counts
  - Don't stick them all in lost+found (unless media failure)

An alternative: Journaling

- **Reserve a portion of disk for *write-ahead* log**
  - Write any metadata operation first to log, then to disk
  - After crash/reboot, re-play the log (efficient)
  - My re-do already committed change, but won't miss anything
- **Performance advantage:**
  - Log is consecutive portion of disk
  - Multiple log writes very fast (at disk b/w)
  - Consider updates committed when written to log
- **Example: delete directory tree**
  - Record all freed blocks, changed directory entries in log
  - Return control to user
  - Write out changed directories, bitmaps, etc. in background (sort for good disk arm scheduling)

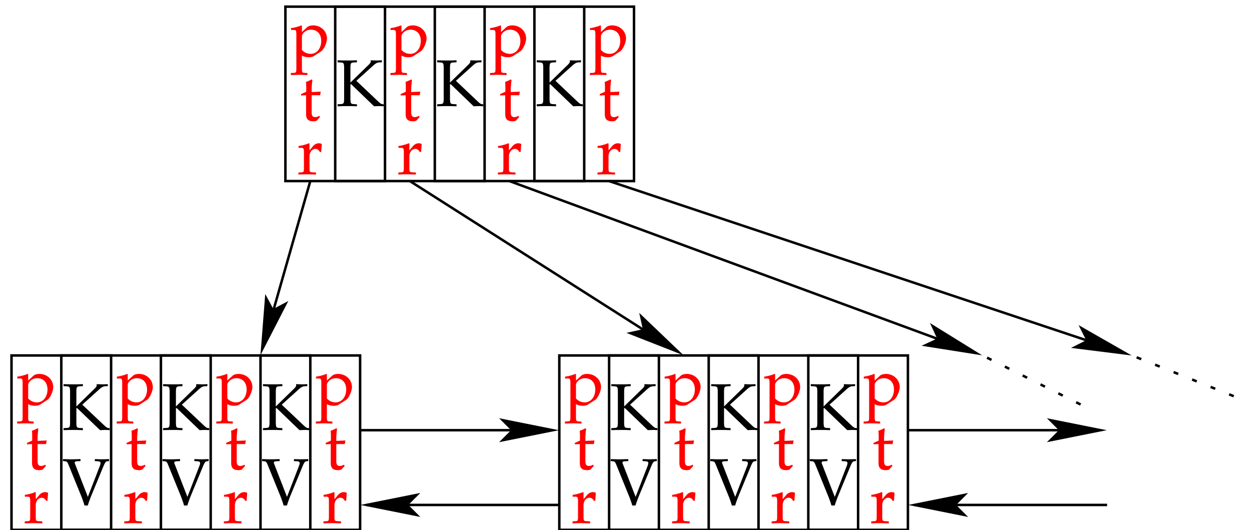
Journaling details

- **Must find oldest relevant log entry**
  - Otherwise, redundant and slow to replay whole log
- **Use checkpoints**
  - Once all records up to log entry N have been processed and affected blocks stably committed to disk…
  - Record N to disk either in reserved checkpoint location, or in checkpoint log record
  - Never need to go back before most recent checkpointed N
- **Must also find end of log**
  - Typically circular buffer; don't play old records out of order
  - Can include begin transaction/end transaction records
  - Also typically have checksum in case some sectors bad

Case study: XFS [Sweeney]

- **Main idea: Think big**
  - Big disks, files, large # of files, 64-bit everything
  - Yet maintain very good performance
- **Break disk up into *Allocation Groups* (AGs)**
  - 0.5 – 4 GB regions of disk
  - New directories go in new AGs
  - Within directory, inodes of files go in same AG
  - Unlike cylinder groups, AGs too large to minimize seek times
  - Unlike cylinder groups, no fixed # of inodes per AG
- **Advantages of AGs:**
  - Parallelize allocation of blocks/inodes on multiprocessor (independent locking of different free space structures)
  - Can use 32-bit block pointers within AGs (keeps data structures smaller)

B+-trees



- **XFS makes extensive use of B+-trees**
  - Indexed data structure stores ordered Keys & Values
  - Keys must have an ordering defined on them
  - Stored data in blocks for efficient disk access
- **For B+-tree w. n items, all operation $O(\log n)$:**
  - Retrieve closest ⟨key, value⟩ to target key k
  - Insert a new ⟨key, value⟩ pair
  - Delete ⟨key, value⟩ pair

B+-trees continued

- **See any algorithms book for details (e.g., [Cormen])**
- **Some operations on B-tree are complex:**
  - E.g., insert item into completely full B+-tree
  - May require "splitting" nodes, adding new level to tree
  - Would be bad to crash & leave B+tree in inconsistent state
- **Journal enables atomic complex operations**
  - First write all changes to the log
  - If crash while writing log, incomplete log record will be discarded, and no change made
  - Otherwise, if crash while updating B+-tree, will replay entire log record and write everything

B+-trees in XFS

- **B+-trees are complex to implement**
  - But once you've done it, might as well use everywhere
- **Use B+-trees for directories (keyed on filename hash)**
  - Makes large directories efficient
- **Use B+-trees for inodes**
  - No more FFS-style fixed block pointers
  - Instead, B+-tree maps: file offset $\rightarrow$ $\langle$start block, # blocks$\rangle$
  - Ideally file is one or small number of contiguous extents
  - Allows small inodes & no indirect blocks even for huge files
- **Use to find inode based on inumber**
  - High bits of inumber specify AG
  - B+-tree in AG maps: starting i# $\rightarrow$ $\langle$block #, free-map$\rangle$
  - So free inodes tracked right in leaf of B+-tree

More B+-trees in XFS

- **Free extents tracked by *two* B+-trees**
  1. start block # → # free blocks
  2. # free blocks → # start blocks #
- **Use journal to update both atomically & consistently**
- **#1 allows you to coalesce adjacent free regions**
- **#1 allows you to allocate near some target**
  - E.g., when extending file, but next block near previous one
  - When first writing to file, but data near inode
- **#2 allows you to do best fit allocation**
  - Leave large free extents for large files

Contiguous allocation

- **Ideally want each file contiguous on disk**
  - Sequential file I/O should be as fast as sequential disk I/O
- **But how do you know how large a file will be?**
- **Idea: delayed allocation**
  - *write* syscall only affects the buffer cache
  - Allow write into buffers before deciding where to place on disk
  - Assign disk space only when buffers are flushed
- **Other advantages:**
  - Short-lived files never need disk space allocated
  - *mmap*ed files often written in random order in memory, but will be written to disk mostly contiguously
  - Write clustering: find other nearby stuff to write to disk
