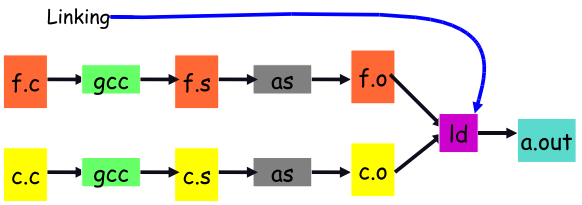
Today's Big Adventure



- How to name and refer to things that don't exist yet
- How to merge separate name spaces into a cohesive whole

- **Readings**
  - man a.out & elf on a Solaris machine
  - run "nm" or "objdump" on a few .o and a.out files.

Linking as our first naming system

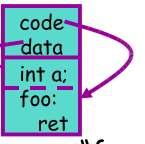
- **Naming is a very deep theme that comes up everywhere**
- **Naming system: maps names to values**
- **Examples:**
  - Linking: Where is printf? How to refer to it? How to deal with synonyms? What if it doesn't exist?
  - Virtual memory address (name) resolved to physical address (value) using page table
  - File systems: translating file and directory names to disk locations, organizing names so you can navigate, . . .
  - www.stanford.edu resolved 171.67.22.34 using DNS
  - Street names: translating (elk, pine, . . .) vs (1st, 2nd, . . .) to actual location
  - Your name resolved to grade (value) using spreadsheet

Perspectives on memory contents

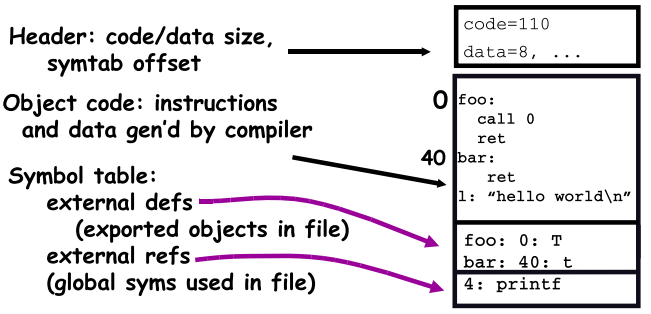
- **Programming language view:** `x += 1;  add r1,r1,1`
  - Instructions: Specify operations to perform
  - Variables: Operands that can change over time
  - Constants: Operands that never change
- **Changeability view (for sharing):**
  - read only: code, constants (maybe one copy for all processes)
  - read/write: variables (each process needs own copy)
- **Addresses versus data:**
  - Addresses used to locate something: must update it if you move
  - Examples: linkers, garbage collectors, changing apartment
- **Binding time: When is a value determined/computed?**
  - Early to late: compile time, link time, load time, runtime

How is a process specified?

- **Executable file: the linker/OS interface.**
  - What is code? What is data?
  - Where should they live?



- **Linker builds executables from object files:** "foo.o"



How is a program executed?

- **On Unix systems, read by "loader"**

  - Reads all code/data segs into buffer cache;
    Maps code (read only) and initialized data (r/w) into addr space
  - Or. . . fakes process state to look like paged out
- **Lots of optimizations happen in practice:**
  - Zero-initialized data does not need to be read in.
  - Demand load: wait until code used before get from disk
  - Copies of same program running? Share code
  - Multiple programs use same routines: share code (harder)

What does a process look like? (Unix)

- **Process address space divided into "segments"**
  - text (code), data, heap (dynamic data), and stack

  - Why? (1) different allocation patterns; (2) separate code/data

Who builds what?

- **Heap: allocated and laid out at runtime by malloc**
  - Compiler, linker not involved other than saying where it can start
  - Namespace constructed dynamically and managed by programmer (names stored in pointers, and organized using data structures)
- **Stack: alloc at runtime (proc call), layout by compiler**
  - Names are relative off of stack (or frame) pointer
  - Managed by compiler (alloc on proc entry, free on exit)
  - Linker not involved because name space entirely local: Compiler has enough information to build it.
- **Global data/code: alloc by compiler, layout by linker**
  - Compiler emits them and can form symbolic references between them ("jalr _printf")
  - Linker lays them out, and translates references

Linkers (Linkage editors)

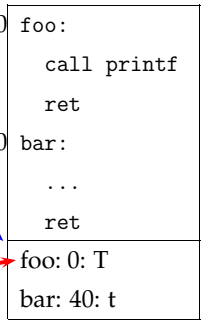
- **Unix: ld**
  - Usually hidden behind compiler
  - Run `gcc -v hello.c` to see ld or invoked (may see collect2)
- **Three functions:**
  - Collect together all pieces of a program
  - Coalesce like segments
  - fix addresses of code and data so the program can run
- **Result: runnable program stored in new object file**
- **Why can't compiler do this?**
  - Limited world view: one file, rather than all files
- **Usually linkers don't rearrange segments, but can**
  - E.g., re-order instructions for fewer cache misses; remove routines that are never called from a.out

Simple linker: two passes needed

- **Pass 1:**
  - Coalesce like segments; arrange in non-overlapping mem.
  - Read file's symbol table, construct global symbol table with entry for every symbol used or defined
  - Compute virtual address of each segment (at start+offset)
- **Pass 2:**
  - Patch references using file and global symbol table
  - Emit result
- **Symbol table: information about program kept while linker running**
  - Segments: name, size, old location, new location
  - Symbols: name, input segment, offset within segment

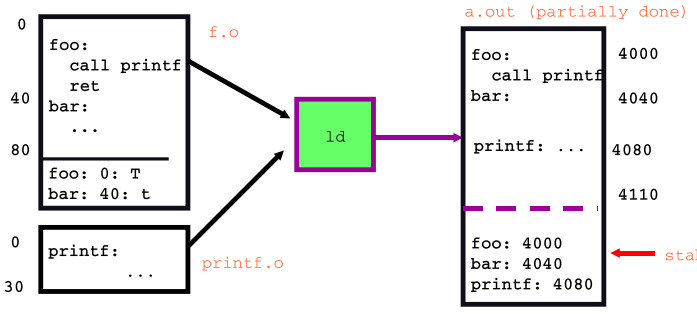
Where to put emitted objects?

- **Compiler:**
  - Doesn't know where data/code should be placed in the process's address space
  - Assumes everything starts at zero
  - Emits symbol table that holds the name and offset of each created object
  - Routine/variables exported by the file are recorded global definition
- **Simpler perspective:**
  - Code is in a big char array
  - Data is in another big char array
  - Compiler creates (object name, index) tuple for each interesting thing
  - Linker then merges all of these arrays



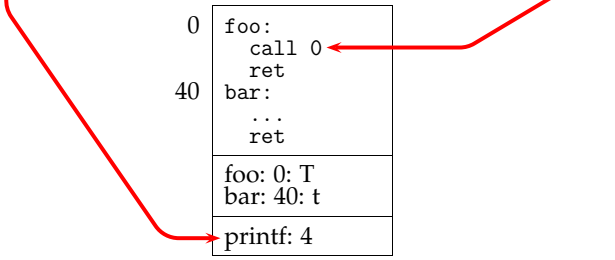
Where to put emitted objects

- **At link time, linker**
  - Determines the size of each segment and the resulting address to place each object at
  - Stores all global definitions in a global symbol table that maps the definition to its final virtual address



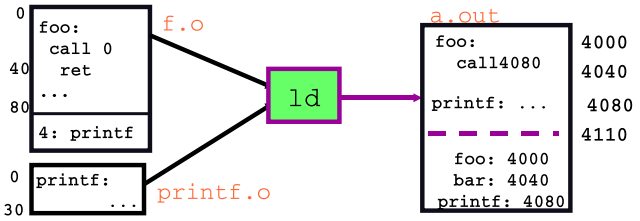
Where is everything?

- **How to call procedures or reference variables?**
  - E.g., call to printf needs a target addr
  - Compiler (actually assembler) places a 0 for the address
  - Emits an external reference telling the linker the instruction's offset and the symbol it needs
- **At link time the linker patches every reference**



Linker: Where is everything

- **At link time the linker**
  - Records all references in the global symbol table
  - After reading all files, each symbol should have exactly one definition and 0 or more uses
  - The linker then enumerates all references and fixes them by inserting their symbol's virtual address into the reference's specified instruction or data location



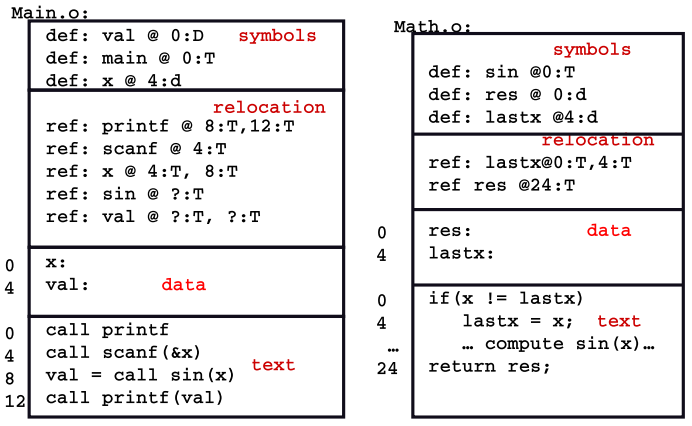
Example: 2 modules and C lib

```
main.c:
  extern float sin();
  extern int printf(), scanf();
  float val = 0.0;
  main() {
    static float x = 0.0;
    printf("enter number");
    scanf("%f", &x);
    val = sin(x);
    printf("Sine is %f", val);
  }
```

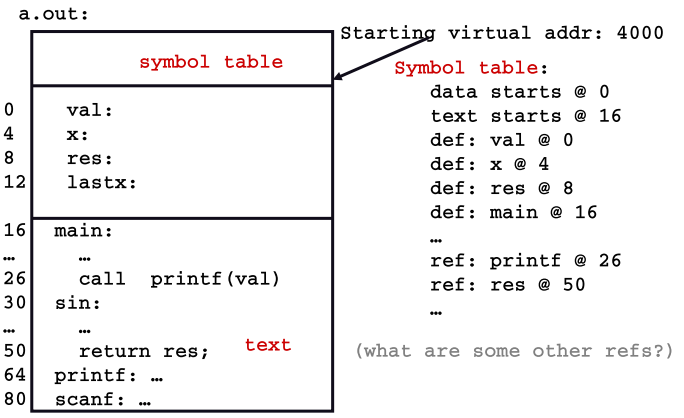
```
C library:
  int scanf(char *fmt, ...) { ... }
  int printf(char *fmt, ...) { ... }
```

```
math.c:
  float sin(float x) {
      float tmp1, tmp2;
      static float res = 0.0;
      static float lastx = 0.0;
      if(x != lastx) {
        lastx = x;
        ... compute sin(x)...
      }
      return res;
  }
```

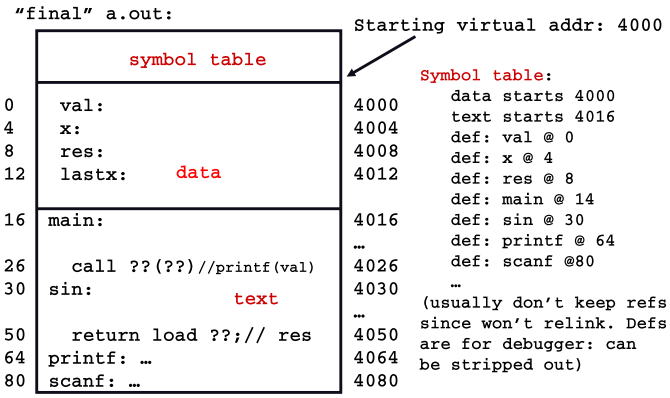
Initial object files



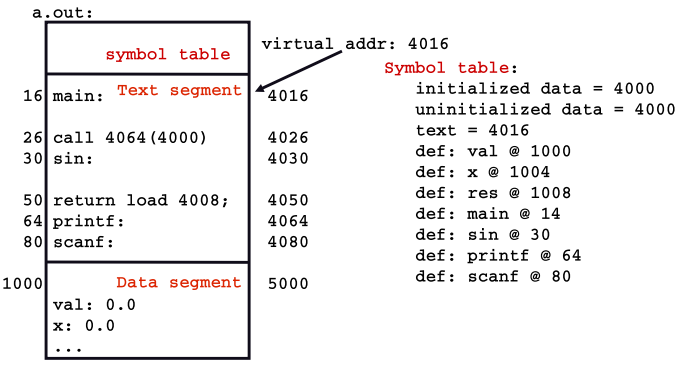
Pass 1: Linker reorganization



Pass 2: Relocation



What gets written out



Examining programs with nm

```
int uninitialized;
int initialized = 1;
const int constant = 2;
int main ()
{
  return 0;
}
```

```
% nm a.out
...
0400400 T _start
04005bc R constant
0601008 W data_start
0601020 D initialized
04004b8 T main
0601028 B uninitialized
```

VA

symbol type

- `const` **variables of type R won't be written**
  - Note `constant` VA on same page as `main`
  - Share pages of read-only data just like text
- **Uninitialized data in "BSS" segment, B**
  - No actual contents in executable file
  - Goes in pages that the OS allocates zero-filled, on-demand

Examining programs with objdump

Note Load mem addr. and File off have same page alignment for easy mmaping

```
% objdump -h a.out
a.out:     file format elf64-x86-64
Sections:
Idx Name    Size      VMA       LMA       File off  Algn
...
 12 .text   000001a8  00400400  00400400  00000400  2**4
            CONTENTS, ALLOC, LOAD, READONLY, CODE
...
 14 .rodata 00000008  004005b8  004005b8  000005b8  2**2
            CONTENTS, ALLOC, LOAD, READONLY, DATA
...
 17 .ctors  00000010  00600e18  00600e18  00000e18  2**3
            CONTENTS, ALLOC, LOAD, DATA
...
 23 .data   0000001c  00601008  00601008  00001008  2**3
            CONTENTS, ALLOC, LOAD, DATA
...
 24 .bss    0000000c  00601024  00601024  00001024  2**2
            ALLOC
...
```

No contents in file

Types of relocation

- **Place final address of symbol here**
  - Example: extern int y, x = &y;
    y gets address in BSS, x in data segment, contains VA of y
  - code example: call foo becomes call 0x44
    computed virtual address of foo is stuffed in the binary encoding of "call"
- **Add address of symbol to contents of this location**
  - used for record/struct offsets
  - example: q.head = 1 to move #1, q+4 to move #1, 0x64
- **Add diff between final and original seg to this location**
  - segment was moved, "static" variables need to be reloc'ed

Name mangling

Mangling not compatible across compiler versions

```
// C++
int foo (int a)
{
  return 0;
}
int foo (int a, int b)
{
  return 0;
}
```

```
% nm overload.o
0000000 T _Z3fooi
000000e T _Z3fooii
        U __gxx_personality_v0
```

Unmangle names

```
% nm overload.o | c++filt
0000000 T foo(int)
000000e T foo(int, int)
        U __gxx_personality_v0
```

- **C++ can have many functions with the same name**
- **Compiler therefore *mangles* symbols**
  - Makes a unique name for each function
  - Also used for methods/namespaces (`obj::fn`), template instantiations, & special functions such as `operator new`

Initialization and destruction

```
// C++
int a_foo_exists;
struct foo_t {
  foo_t () {
    a_foo_exists = 1;
  }
};
foo_t foo;
```

- **Initializers run before main**
  - Mechanism is platform-specific
- **Example implementation:**
  - Compiler emits static function in each file running initializers
  - Wrap linker with `collect2` program that generates `___main` function calling all such functions
  - Compiler inserts call to `___main` when compiling real `main`

```
% cc -S -o- ctor.C | c++filt
...
        .text
        .align 2
__static_initialization_and_destruction_0(int, int):
...
        call    foo_t::foo_t()
```

Other information in executables

```
// C++
struct foo_t {
  ~foo_t () {/*...*/}
};

void fn ()
{
  foo_t foo;
  { /*...*/
    throw (0);
  }
}
```

- **Throwing exceptions destroys automatic variables**
- **Must find all such variables**
  - All procedure's call frames until exception caught
  - All variables of types with non-trivial destructors
- **Record info in special sections**
- **Executables can include debug info (compile w. –g)**
  - What source line does each binary instruction correspond to?

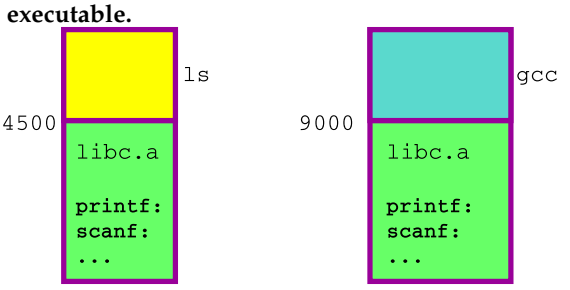
Variation 0: Dynamic linking

- **Link time isn't special, can link at runtime too**
  - Get code not available when program compiled
  - Defer loading code until needed

  - Issues: what happens if can't resolve? How can behavior differ compared to static linking? Where to get unresolved syms (e.g., "puts") from?

Variation 1: Static shared libraries

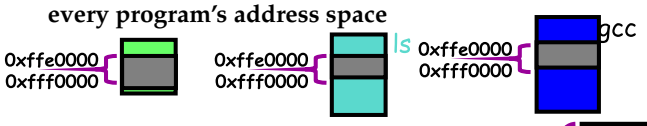
- **Observation: everyone links in standard libraries (libc.a.), these libs consume space in every executable.**



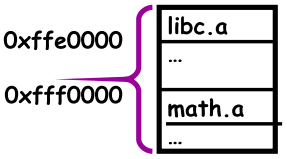
- **Insight: we can have a single copy on disk if we don't actually include lib code in executable**

Static shared libraries

- **Define a "shared library segment" at same address in every program's address space**



- Every shared lib is allocated a unique range in this seg, and computes where its external defs reside
- Linker links program against lib (why?) but does not bring in actual code



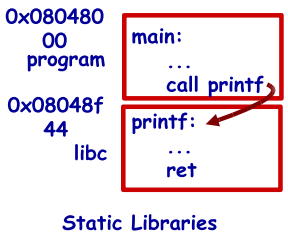
- Loader marks shared lib region as unreadable
- When process calls lib code, seg faults: embedded linker brings in lib code from known place & maps it in.
- Now different running programs can now share code!

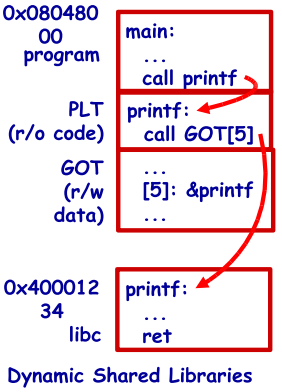
Variation 2: Dynamic shared libs

- **Static shared libraries require system-wide pre-allocation of address space**
  - Clumsy, inconvenient
  - What if a library gets too big for its space?
  - Can space ever be reused?
- **Solution: Dynamic shared libraries**
  - Let any library be loaded at any VA
  - New problem: Linker won't know what names are valid
  - Solution: stub library
  - New problem: How to call functions if their position may vary?
  - Solution: next page…

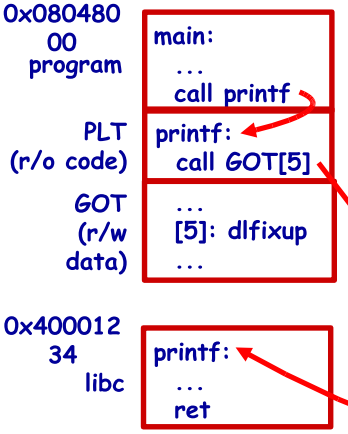
Position-independent code

- **Code must be able to run anywhere in virtual mem**
- **Runtime linking would prevent code sharing, so...**
- **Add a level of indirection!**





Lazy dynamic linking



- **Linking all the functions at startup costs time**
- **Program might only call a few of them**
- **Only link each function on its first call**

Code = data, data = code

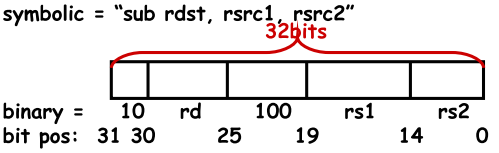
- **No inherent difference between code and data**
  - Code is just something that can be run through a CPU without causing an "illegal instruction fault"
  - Can be written/read at runtime just like data "dynamically generated code"
- **Why? Speed (usually)**
  - Big use: eliminate interpretation overhead. Gives 10-100x performance improvement
  - Example: Just-in-time compilers for java.
  - In general: optimizations thrive on information. More information at runtime.
- **The big tradeoff:**
  - Total runtime = code gen cost + cost of running code

How?

- **Determine binary encoding of desired instructions**

SPARC: sub instruction

symbolic = "sub rdst, rsrc1, rsrc2"



- **Write these integer values into a memory buffer**

```
unsigned code[1024], *cp = &code[0];
/* sub %g5, %g4, %g3 */
*cp++ = (2<<30) | (5<<25) | (4<<19) |(4<<14) | 3;
...
```

- **Jump to the address of the buffer:**

```
((int (*)())code)();
```

Linking and security

```
void fn ()
{
  char buf[80];
  gets (buf);
  /* ... */
}
```

1. **Attacker puts code in buf**
   - Overwrites return address to jump to code
2. **Attacker puts shell command above buf**
   - Overwrites return address so function "returns" to `system` function in libc

- **People try to address problem with linker**
- **W^X: Make memory both writable and executable**
  - Prevents 1 but not 2, breaks jits
- **Address space randomization**
  - Makes attack #2 a little harder, not impossible

Linking Summary

- **Compiler: generates 1 object file for each source file**
  - Problem: incomplete world view
  - Where to put variables and code? How to refer to them?
  - Names definitions symbolically ("printf"), refers to routines/variable by symbolic name
- **Linker: combines all object files into 1 executable file**
  - big lever: global view of everything. Decides where everything lives, finds all references and updates them
  - Important interface with OS: what is code, what is data, where is start point?
- **OS loader reads object files into memory:**
  - allows optimizations across trust boundaries (share code)
  - provides interface for process to allocate memory (sbrk)
