1. Cache coherence – the hardware view
2. Synchronization and memory consistency review
3. C11 Atomics
4. Avoiding locks
Important memory system properties

- **Coherence** – concerns accesses to a single memory location
  - Must obey program order if access from only one CPU
  - There is a total order on all updates
  - There is bounded latency before everyone sees a write

- **Consistency** – concerns ordering across memory locations
  - Even with coherence, different CPUs can see the same write happen at different times
  - Sequential consistency is what matches our intuition (As if operations from all CPUs interleaved on one CPU)
  - Many architectures offer weaker consistency
  - Yet well-defined weaker consistency can still be sufficient to implement [thread API contract from concurrency lecture](#)
Multicore cache coherence

• **Performance requires caches**
  - Divided into chunks of bytes called lines (e.g., 64 bytes)
  - Caches create an opportunity for cores to disagree about memory

• **Bus-based approaches**
  - “Snoopy” protocols, each CPU listens to memory bus
  - Use write-through and invalidate when you see a write bits
  - Bus-based schemes limit scalability

• **Modern CPUs use networks (e.g., hypertransport, QPI, UPI)**
  - CPUs pass each other messages about cache lines
MESI coherence protocol

- **Modified**
  - Exactly one cache has a valid copy
  - That copy is dirty (needs to be written back to memory)
  - Must invalidate all copies in other caches before entering this state

- **Exclusive**
  - Same as Modified except the cache copy is clean

- **Shared**
  - One or more caches and memory have a valid copy

- **Invalid**
  - Doesn’t contain any data

- **Owned (for enhanced “MOESI” protocol)**
  - Memory may contain stale value of data (like Modified state)
  - But have to broadcast modifications (sort of like Shared state)
  - Can have one owned + multiple shared copies of cache line
Core and Bus Actions

- **Actions performed by CPU core**
  - Read
  - Write
  - Evict (modified? must write back)

- **Transactions on bus (or interconnect)**
  - Read: without intent to modify, data can come from memory or another cache
  - Read-exclusive: with intent to modify, must invalidate all other cache copies
  - Writeback: contents put on bus and memory is updated
cc-NUMA

- Old machines used *dance hall* architectures
  - Any CPU can “dance with” any memory equally

- An alternative: Non-Uniform Memory Access (NUMA)
  - Each CPU has fast access to some “close” memory
  - Slower to access memory that is farther away
  - Use a directory to keep track of who is caching what

- Originally for esoteric machines with many CPUs
  - But AMD and then intel integrated memory controller into CPU
  - Faster to access memory controlled by the local socket
    (or even local die in a multi-chip module)

- cc-NUMA = cache-coherent NUMA
  - Rarely see non-cache-coherent NUMA (BBN Butterfly 1, Cray T3D)
Real World Coherence Costs

- See [David] for a great reference. Xeon results:
  - 3 cycle L1, 11 cycle L2, 44 cycle LLC, 355 cycle local RAM

- If another core in same socket holds line in modified state:
  - load: 109 cycles (LLC + 65)
  - store: 115 cycles (LLC + 71)
  - atomic CAS: 120 cycles (LLC + 76)

- If a core in a different socket holds line in modified state:
  - NUMA load: 289 cycles
  - NUMA store: 320 cycles
  - NUMA atomic CAS: 324 cycles

- But only a partial picture
  - Could be faster because of out-of-order execution
  - Could be slower if interconnect contention or multiple hops
NUMA and spinlocks

- Test-and-set spinlock has several advantages
  - Simple to implement and understand
  - One memory location for arbitrarily many CPUs

- But also has disadvantages
  - Lots of traffic over memory interconnect (especially w. > 1 spinner)
  - Not necessarily fair (lacks bounded waiting)
  - Even less fair on a NUMA machine

- Idea 1: Avoid spinlocks altogether (today)

- Idea 2: Reduce interconnect traffic with better spinlocks (next lecture)
  - Design lock that spins only on local memory
  - Also gives better fairness
1. Cache coherence – the hardware view
2. Synchronization and memory consistency review
3. C11 Atomics
4. Avoiding locks
Amdahl’s law

\[ T(n) = T(1) \left( B + \frac{1}{n}(1 - B) \right) \]

- **Expected speedup limited when only part of a task is sped up**
  - \( T(n) \): the time it takes \( n \) CPU cores to complete the task
  - \( B \): the fraction of the job that must be serial

- **Even with massive multiprocessors**, \( \lim_{n \to \infty} = B \cdot T(1) \)</n
- Places an ultimate limit on parallel speedup

- **Problem**: synchronization increases serial section size
mutex_t m;
lock(&m);
cnt = cnt + 1; /* critical section */
unlock(&m);

- Only one thread can hold a mutex at a time
  - Makes critical section atomic

- Recall thread API contract
  - All access to global data must be protected by a mutex
  - Global = two or more threads touch data and at least one writes

- Means must map each piece of global data to one mutex
  - Never touch the data unless you locked that mutex

- But many ways to map data to mutexes
Locking granularity

Consider two lookup implementations for global hash table:

```c
struct list *hash_tbl[1021];
```

**coarse-grained locking**

```c
mutex_t m;
:
mutex_lock(&m);
struct list_elem *pos = list_begin (hash_tbl[hash(key)]);
/* ... walk list and find entry ... */
mutex_unlock(&m);
```

**fine-grained locking**

```c
mutex_t bucket_lock[1021];
:
int index = hash(key);
mutex_lock(&bucket_lock[index]);
struct list_elem *pos = list_begin (hash_tbl[index]);
/* ... walk list and find entry ... */
mutex_unlock(&bucket_lock[index]);
```

• Which implementation is better?
• Fine-grained locking admits more parallelism
  - E.g., imagine network server looking up values in hash table
  - Parallel requests will usually map to different hash buckets
  - So fine-grained locking should allow better speedup

• When might coarse-grained locking be better?
• Fine-grained locking admits more parallelism
  - E.g., imagine network server looking up values in hash table
  - Parallel requests will usually map to different hash buckets
  - So fine-grained locking should allow better speedup

• When might coarse-grained locking be better?
  - Suppose you have global data that applies to whole hash table

    struct hash_table {
      size_t num_elements; /* num items in hash table */
      size_t num_buckets; /* size of buckets array */
      struct list *buckets; /* array of buckets */
    };

    - Read `num_buckets` each time you insert
    - Check `num_elements` each insert, possibly expand buckets & rehash
    - Single global mutex would protect these fields

• Can you avoid serializing lookups to hash table?
Recall a mutex allows access in only one thread

But a data race occurs only if
- Multiple threads access the same data, and
- At least one of the accesses is a write

How to allow multiple readers or one single writer?
- Need lock that can be shared amongst concurrent readers

Can implement using other primitives (next slides)
- Keep integer \( i \) – # of readers or -1 if held by writer
- Protect \( i \) with mutex
- Sleep on condition variable when can’t get lock
Implementing shared locks

```c
struct sharedlk {
    int i;    /* # shared lockers, or -1 if exclusively locked */
    mutex_t m;
    cond_t c;
};

void AcquireExclusive (sharedlk *sl) {
    lock (&sl->m);
    while (sl->i) { wait (&sl->m, &sl->c); }
    sl->i = -1;
    unlock (&sl->m);
}

void AcquireShared (sharedlk *sl) {
    lock (&sl->m);
    while (&sl->i < 0) { wait (&sl->m, &sl->c); }
    sl->i++;
    unlock (&sl->m);
}
```
void ReleaseShared (sharedlk *sl) {
    lock (&sl->m);
    if (!--sl->i)
        signal (&sl->c);
    unlock (&sl->m);
}

void ReleaseExclusive (sharedlk *sl) {
    lock (&sl->m);
    sl->i = 0;
    broadcast (&sl->c);
    unlock (&sl->m);
}

• Any issues with this implementation?
void ReleaseShared (sharedlk *sl) {
    lock (&sl->m);
    if (!--sl->i)
        signal (&sl->c);
    unlock (&sl->m);
}

void ReleaseExclusive (sharedlk *sl) {
    lock (&sl->m);
    sl->i = 0;
    broadcast (&sl->c);
    unlock (&sl->m);
}

• Any issues with this implementation?
  - Prone to starvation of writer (no bounded waiting)
  - How might you fix?
struct var {
    int lock;
    int val;
};

void atomic_inc (var *v) {
    while (test_and_set (&v->lock))
        ;
    v->val++;
    v->lock = 0;
}

void atomic_dec (var *v) {
    while (test_and_set (&v->lock))
        ;
    v->val--;
    v->lock = 0;
}

- Is this code correct without sequential consistency?
Memory reordering danger

- Suppose no sequential consistency (& don’t compensate)
- Hardware could violate program order

Program order on CPU #1

v->lock = 1;
register = v->val;
v->val = register + 1;
v->lock = 0;

View on CPU #2

v->lock = 1;
v->lock = 0;
/* danger */;
v->val = register + 1;

- If atomic_inc called at /* danger */, bad val ensues!
void atomic_inc (var *v) {
    while (test_and_set (&v->lock))
    ;
    v->val++;
    /* danger */
    v->lock = 0;
}

• Must ensure all CPUs see the following:
  1. v->lock = 1 ran before v->val was read and written
  2. v->lock = 0 ran after v->val was written

• How does #1 get assured on x86?
  - Recall test_and_set uses xchgl %eax, (%edx)

• How to ensure #2 on x86?
void atomic_inc (var *v) {
    while (test_and_set (&v->lock))
    ;
    v->val++;
    /* danger */
    v->lock = 0;
}

• Must ensure all CPUs see the following:
  1. v->lock = 1 ran before v->val was read and written
  2. v->lock = 0 ran after v->val was written

• How does #1 get assured on x86?
  - Recall test_and_set uses xchgl %eax, (%edx)
  - xchgl instruction always “locked,” ensuring barrier

• How to ensure #2 on x86?
void atomic_inc (var *v) {
    while (test_and_set (&v->lock))
    ;
    v->val++;
    asm volatile ("sfence" ::: "memory");
    v->lock = 0;
}

• Must ensure all CPUs see the following:
  1. v->lock = 1 ran before v->val was read and written
  2. v->lock = 0 ran after v->val was written

• How does #1 get assured on x86?
  - Recall test_and_set uses xchgl %eax, (%edx)
  - xchgl instruction always “locked,” ensuring barrier

• How to ensure #2 on x86?
  - Might need fence instruction after, e.g., non-temporal stores
  - Definitely need compiler barrier
asm volatile (template-string : outputs : inputs : clobbers);

- Puts *template-string* in assembly language compiler output
  - Expands %0, %1, … (a bit like printf conversion specifiers)
  - Use “%%” for a literal % (e.g., “%%cr3” to specify %cr3 register)
- *inputs/output* specifies parameters as "constraint" (*value*)
  ```
  int outvar, invar = 3;
  asm ("movl %1, %0" : "=r" (outvar) : "r" (invar));
  /* now outvar == 3 */
  ```
- *clobbers* lists other state that get used/overwritten
  - Special value "memory" prevents reordering with loads & stores
  - Serves as compiler barrier, as important as hardware barrier
- *volatile* indicates side effects other than result
  - Otherwise, gcc might optimize away if you don’t use result
Correct spinlock on alpha

- Recall implementation of `test_and_set` on alpha (with much weaker memory consistency than x86):

  ```
  _test_and_set:
    ldq_l v0, 0(a0)  # v0 = *lockp (LOCKED)
    bne v0, 1f       # if (v0) return
    addq zero, 1, v0 # v0 = 1
    stq_c v0, 0(a0)  # *lockp = v0 (CONDITIONAL)
    beq v0, _test_and_set # if (failed) try again
    mb
    addq zero, zero, v0 # return 0
  1: ret zero, (ra), 1
  ```

- **Memory barrier instruction** `mb` (like `mfence`)
  - All processors will see that everything before `mb` in program order happened before everything after `mb` in program order

- Need barrier before releasing spinlock as well:

  ```
  asm volatile("mb" ::: "memory");
  v->lock = 0;
  ```
Memory barriers/fences

- Fortunately, consistency need not overly complicate code
  - If you do locking right, only need a few fences within locking code
  - Code will be easily portable to new CPUs

- Most programmers should stick to mutexes

- But advanced techniques may require lower-level code
  - Later this lecture will see some wait-free algorithms
  - Also important for optimizing special-case locks
    (E.g., Linux kernel rw_semaphore, ...)

- Algorithms often explained assuming sequential consistency
  - Must know how to use memory fences to implement correctly
  - E.g., see [Howells] for how Linux deals with memory consistency
  - And another plug for Why Memory Barriers

- Next: How C11 allows portable low-level code
1 Cache coherence – the hardware view
2 Synchronization and memory consistency review
3 C11 Atomics
4 Avoiding locks
Atomics and portability

• Lots of variation in atomic instructions, consistency models, compiler behavior
  - Changing the compiler or optimization level can invalidate code

• Different CPUs today: Your laptop is x86, but cell phone ARM
  - x86: Total Store Order Consistency Model, CISC
  - arm: Relaxed Consistency Model, RISC

• Could make it impossible to write portable kernels and applications

• Fortunately, the C11 standard has builtin support for atomics
  - Enable in GCC with the -std=gnu11 flag (now the default)

• Also available in C++11, but won’t discuss today
• Within a thread, many evaluations are *sequenced*
  - E.g., in “f1(); f2();”, evaluation of f1 is sequenced before f2
• Across threads, some operations *synchronize with others*
  - E.g., releasing mutex m synchronizes with a subsequent acquire m
• **Evaluation** A *happens before* B, which we’ll write A → B, when:
  - A is sequenced before B (in the same thread),
  - A synchronizes with B,
  - A is dependency-ordered before B (ignore for now—means A has release semantics and B consume semantics for same value), or
  - There is another operation X such that A → X → B.¹

¹Except chain of “→” cannot end: …, dependency-ordered, sequenced before
C11 Atomics: Big picture

- C11 says behavior of a data race is undefined
  - A write conflicts with a read or write of same memory location
  - Two conflicting operations race if not ordered by happens before
  - Undefined can be anything (e.g., delete all your files, …)

- Spinlocks (and hence mutexes that internally use spinlocks) synchronize across threads
  - Synchronization adds happens before arrows, avoiding data races

- Yet hardware supports other means of synchronization

- C11 atomics provide direct access to synchronized lower-level operations
  - E.g., can get compiler to issue lock prefix in some cases
C11 Atomics: Basics

- **Include new `<stdatomic.h>` header**
- **New `__Atomic` type qualifier:** e.g., `__Atomic int foo;`
  - Convenient aliases: `atomic_bool`, `atomic_int`, `atomic_ulong`, ...
  - Must initialize specially:
    ```c
    #include <stdatomic.h>
    __Atomic int global_int = ATOMIC_VAR_INIT(140);
    :;
    __Atomic(int) *dyn = malloc(sizeof(*dyn));
    atomic_init(dyn, 140);
    ```
- **Compiler emits read-modify-write instructions for atomics**
  - E.g., `+=`, `-=` `|=`, `&=`, `^=`, `++`, `--` do what you would hope
  - Act atomically and synchronize with one another
- **Also functions including** `atomic_fetch_add`, `atomic_compare_exchange_strong`, ...
Locking and atomic flags

- Implementations might use spinlocks internally for most atomics
  - Could interact badly with interrupt/signal handlers
  - Can check if ATOMIC_INT_LOCK_FREE, etc., macros defined
  - Fortunately modern CPUs don’t require this

- **atomic_flag** is a special type guaranteed lock-free
  - Boolean value without support for loads and stores
  - Initialize with: `atomic_flag mylock = ATOMIC_FLAG_INIT;`
  - Only two kinds of operation possible:
    - `_Bool atomic_flag_test_and_set(volatile atomic_flag *obj);`
    - `void atomic_flag_clear(volatile atomic_flag *obj);`
  - Above functions guarantee sequential consistency (atomic operation serves as memory fence, too)
enum memory_order { /*...*/ }; 

_Bool atomic_flag_test_and_set_explicit(
    volatile atomic_flag *obj, memory_order order);
void atomic_flag_clear_explicit(
    volatile atomic_flag *obj, memory_order order);

C atomic_load_explicit(
    const volatile A *obj, memory_order order);
void atomic_store_explicit(
    volatile A *obj, C desired, memory_order order);

bool atomic_compare_exchange_weak_explicit(
    A *obj, C *expected, C desired,
    memory_order order succ, memory_order order fail);

• Atomic functions have _explicit variants
  - These guarantee coherence but not sequential consistency
  - May allow compiler to generate faster code
Memory ordering

- **Six possible memory_order values:**
  1. memory_order_relaxed: no memory ordering
  2. memory_order_consume: super tricky, see [Preshing] for discussion
  3. memory_order_acquire: for start of critical section
  4. memory_order_release: for end of critical section
  5. memory_order_acq_rel: combines previous two
  6. memory_order_seq_cst: full sequential consistency

- Also have fence operation not tied to particular atomic:
  
  ```c
  void atomic_thread_fence(memory_order order);
  ```

- **Suppose thread 1 releases and thread 2 acquires**
  - Thread 1’s preceding accesses can’t move past **release** store
  - Thread 2’s subsequent accesses can’t move before **acquire** load
  - Warning: other threads might see a completely different order
Types of memory fence

- **Load-Load** fence
- **Load-Store** fence
- **Store-Load** fence
- **Store-Store** fence

**Acquire fence**

**Release fence**

**Seq_cst fence**

**Acq_rel fence**

- $X$-$Y$ fence = operations of type $X$ sequenced before the fence happen before operations of type $Y$ sequenced after the fence

---

$^2$Credit to [Preshing](#) for explaining it this way
Example: Atomic counters

```c
_Atomic(int) packet_count;

void recv_packet(...) {
    :
    atomic_fetch_add_explicit(&packet_count, 1, memory_order_relaxed);
    :
}
```

- Need to count packets accurately
- Don’t need to order other memory accesses across threads
- Relaxed memory order can avoid unnecessary overhead
  - Depending on hardware, of course (not x86)
Example: Producer, consumer 1

```c
struct message msg_buf;
_Atomic(_Bool) msg_ready;

void send(struct message *m) {
    msg_buf = *m;
    atomic_thread_fence(memory_order_release);
    /* Prior loads+stores happen before subsequent stores */
    atomic_store_explicit(&msg_ready, 1,
                          memory_order_relaxed);
}

struct message *recv(void) {
    _Bool ready = atomic_load_explicit(&msg_ready,
                                        memory_order_relaxed);
    if (!ready)
        return NULL;
    atomic_thread_fence(memory_order_acquire);
    /* Prior loads happen before subsequent loads+stores */
    return &msg_buf;
}
```
struct message msg_buf;
_Atomic(_Bool) msg_ready;

void send(struct message *m) {
    msg_buf = *m;
    atomic_store_explicit(&msg_ready, 1,
                          memory_order_release);
}

struct message *recv(void) {
    _Bool ready = atomic_load_explicit(&msg_ready,
                                        memory_order_acquire);
    if (!ready)
        return NULL;
    return &msg_buf;
}

- This is potentially faster than previous example
  - E.g., other stores after send can be moved before msg_buf
Example: Test-and-set spinlock

```c
void
spin_lock(atomic_flag *lock)
{
    while(atomic_flag_test_and_set_explicit(lock,
                                             memory_order_acquire))
        ;
}

void
spin_unlock(atomic_flag *lock)
{
    atomic_flag_clear_explicit(lock, memory_order_release);
}
```
Example: Better test-and-set spinlock

```c
void spin_lock(atomic_bool *lock) {
    while(atomic_exchange_explicit(lock, 1, memory_order_acquire)) {
        while(atomic_load_explicit(lock, memory_order_relaxed))
            __builtin_ia32_pause(); /* x86-specific */
    }
}

void spin_unlock(atomic_bool *lock) {
    atomic_store_explicit(lock, 0, memory_order_release);
}
```

- See [Rigtorp] for a good discussion
Outline

1. Cache coherence – the hardware view
2. Synchronization and memory consistency review
3. C11 Atomics
4. Avoiding locks
Recall producer/consumer (lecture 3)

/* PRODUCER */
for (;;) {
    item *nextProduced
        = produce_item ();

    mutex_lock (&mutex);
    while (count == BUF_SIZE)
        cond_wait (&nonfull, &mutex);

    buffer[in] = nextProduced;
    in = (in + 1) % BUF_SIZE;
    count++;
    cond_signal (&nonempty);
    mutex_unlock (&mutex);
}

/* CONSUMER */
for (;;) {
    mutex_lock (&mutex);
    while (count == 0)
        cond_wait (&nonempty, &mutex);

    nextConsumed = buffer[out];
    out = (out + 1) % BUF_SIZE;
    count--;
    cond_signal (&nonfull);
    mutex_unlock (&mutex);
    consume_item (nextConsumed);
}
Eliminating locks

- One use of locks is to coordinate multiple updates of single piece of state

- How to remove locks here?
  - Factor state so that each variable only has a single writer

- Producer/consumer example revisited
  - Assume one producer, one consumer
  - Why do we need `count` variable, written by both?  
    To detect buffer full/empty
  - Have producer write `in`, consumer write `out` (both `_Atomic`)
  - Use `in`/`out` to detect buffer state
  - But note next example busy-waits, which is less good
atomic_int in, out;

void producer (void *ignored) {
    for (;;) {
        item *nextProduced = produce_item ();
        while ((((in + 1) % BUF_SIZE) == out) thread_yield ());
        buffer[in] = nextProduced;
        in = (in + 1) % BUF_SIZE;
    }
}

void consumer (void *ignored) {
    for (;;) {
        while (in == out) thread_yield ();
        nextConsumed = buffer[out];
        out = (out + 1) % BUF_SIZE;
        consume_item (nextConsumed);
    }
}

[Note fences not needed because no relaxed atomics]
void producer (void *ignored) {
    for (;;) {
        item *nextProduced = produce_item ();
        int myin = atomic_load_explicit(&in, memory_order_relaxed);
        for (;;) {
            if ((myin + 1) % BUF_SIZE !=
                atomic_load_explicit(&out, memory_order_relaxed))
                break;
            thread_yield ();
        }
        buffer[myin] = nextProduced;
        atomic_store_explicit(&in, (myin+1) % BUF_SIZE,
                               memory_order_release);
    }
}

void consumer (void *ignored) {
    // use memory_order_acquire when loading in
    // to ensure you get correct buffer[myin] value
}
Non-blocking synchronization

- **Design algorithm to *avoid critical sections***
  - Any threads can make progress if other threads are preempted
  - Which wouldn’t be the case if preempted thread held a lock

- **Requires that hardware provide the right kind of atomics**
  - Simple test-and-set is insufficient
  - Atomic compare and swap is good: \( \text{CAS}(\text{mem}, \text{old}, \text{new}) \)
    
    If \(*\text{mem} == \text{old}, \text{then swap } *\text{mem} \leftarrow \text{new and return true, else false} \)

- **Can implement many common data structures**
  - Stacks, queues, even hash tables

- **Can implement any algorithm on right hardware**
  - Need operation such as atomic compare and swap (has property called *consensus number* = \( \infty \) \cite{Herlihy})
  - Entire kernels have been written without locks \cite{Greenwald}
Example: non-blocking stack

```c
struct item {
    /* data */
    _Atomic (struct item *) next;
};
typedef _Atomic (struct item *) stack_t;

void atomic_push (stack_t *stack, item *i) {
    do {
        i->next = *stack;
    } while (!CAS (stack, i->next, i));
}

item *atomic_pop (stack_t *stack) {
    item *i;
    do {
        i = *stack;
    } while (!CAS (stack, i, i->next));
    return i;
}
```
Wait-free stack issues

```
stack
A
i = *stack;
reg ← i->next

stack
B
C

stack
C
NULL

stack
A'
C
NULL

CAS (stack, i, i->next)

stack
B
garbage

```

- “ABA” race in pop if other thread pops, re-pushes $i$
  - Can be solved by [counters](#) or [hazard pointers](#) to delay re-use
“Benign” races

- Could also eliminate locks by having race conditions

- Maybe you think you care more about speed than correctness

```c
++hits; /* each time someone accesses web site */
```

- Maybe you think you can get away with the race

```c
if (!initialized) {
    lock (m);
    if (!initialized) {
        initialize ();
        atomic_thread_fence (memory_order_release); /* why? */
        initialized = 1;
    }
    unlock (m);
}
```

- But don’t do this [Vyukov], [Boehm]! Not benign at all
  - Get undefined behavior—akin to out-of-bounds array access in C11
  - If needed for efficiency, use relaxed-memory-order atomics
Read-copy update [McKenney]

- Some data is read way more often than written
  - Routing tables consulted for each forwarded packet
  - Data maps in system with 100+ disks (updated on disk failure)

- Optimize for the common case of reading without lock
  - E.g., global variable: `routing_table *rt;`
  - Call `lookup (rt, route);` with no lock

- Update by making copy, swapping pointer
  
  ```
  routing_table *newrt = copy_routing_table (rt);
  update_routing_table (newrt);
  atomic_thread_fence (memory_order_release);
  rt = newrt;
  ```

- Is RCU really safe? Stay tuned next lecture...
Next class

- The exciting conclusion of RCU
  - Spoiler: safe on all architectures except on alpha
- Building a better spinlock
- What interface should kernel provide for sleeping locks?
- Deadlock
- Scalable interface design
