

Administrivia

- Lab 2 due Friday
- Midterm review section Friday
- Midterm exam in class next Monday Feb. 13
 - Open note, but no textbook or electronic devices
 - Bring lecture note printouts
 - If you can't be here, register now (see pinned message in edstem)
- My office hours will be Friday 3pm (zoom only) instead of next Monday

1 / 44

Today's Big Adventure

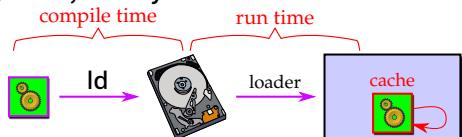

- How to name and refer to things that don't exist yet
- How to merge separate name spaces into a cohesive whole
- More information:
 - How to write shared libraries
 - Run "nm," "objdump," and "readelf" on a few .o and a.out files.
 - The ELF standard
 - Examine /usr/include/elf.h

2 / 44

How is a program executed?

- On Unix systems, read by "loader"

- Reads all code/data segments into buffer cache;
Maps code (read only) and initialized data (r/w) into addr space
- Or...fakes process state to look like paged out

- Lots of optimizations happen in practice:

- Zero-initialized data does not need to be read in.
- Demand load: wait until code used before get from disk
- Copies of same program running? Share code
- Multiple programs use same routines: share code

3 / 44

x86 Assembly syntax

- Linux uses AT&T assembler syntax – places destination last
 - Be aware that intel syntax (used in manual) places destination first
- Types of operand available:
 - Registers start with "%" – `movl %edx,%eax`
 - Immediate values (constants) prefixed by "\$" – `movl $0xff,%edx`
 - `(%reg)` is value at address in register `reg` – `movl (%edi),%eax`
 - `n(%reg)` is value at address in `(register reg)+n` – `movl 8(%ebp),%eax`
 - `*%reg` in an indirection through `reg` – `call *%eax`
 - Everything else is an address – `movl var,%eax; call printf`
- Some heavily used instructions
 - `movl` – moves (copies) value from source to destination
 - `pushl/popl` – pushes/pops value on stack
 - `call` – pushes next instruction address to stack and jumps to target
 - `ret` – pops address of stack and jumps to it
 - `leave` – equivalent to `movl %ebp,%esp; popl %ebp`

4 / 44

Perspectives on memory contents

- Programming language view: `x += 1; add $1, %eax`
 - Instructions: Specify operations to perform
 - Variables: Operands that can change over time
 - Constants: Operands that never change
- Hardware view:
 - `executable`: code, usually read-only
 - `read only`: constants (maybe one copy for all processes)
 - `read/write`: variables (each process needs own copy)
- Need addresses to use data:
 - Addresses locate things. Must update them when you move
 - Examples: linkers, garbage collectors, URL
- Binding time: When is a value determined/computed?
 - Early to late: Compile time, Link time, Load time, Runtime

5 / 44

Running example: hello program

- Hello program
 - Write friendly greeting to terminal
 - Exit cleanly
- Every programming language addresses this problem

[demo]

6 / 44

Running example: hello program

- Hello program
 - Write friendly greeting to terminal
 - Exit cleanly
- Every programming language addresses this problem
- Concept should be familiar if you took 106B:

```
int
main()
{
    cout << "Hello, world!" << endl;
}
```

- Today's lecture: 80 minutes on hello world

```
#include <sys/syscall.h>
int my_errno;
const char greeting[] = "hello world\n";

int my_write(int fd, const void *buf, size_t len)
{
    int ret;
    asm volatile ("int $0x80" : "=a" (ret)
                 : "0" (SYS_write),
                 "b" (fd), "c" (buf), "d" (len)
                 : "memory");
    if (ret < 0) {
        my_errno = -ret;
        return -1;
    }
    return ret;
}

int main() { my_write (1, greeting, my_strlen(greeting)); }
```

6 / 44

7 / 44

Examining hello1.s

- Grab the source and try it yourself
 - tar xzf /afs/ir.stanford.edu/class/cs212/hello.tar.gz
- gcc -S hello1.c produces assembly output in hello1.s
- Check the definitions of my_errno, greeting, main, my_write
- .globl symbol makes symbol global
- Sections of hello1.s are directed to various segments
 - .text says put following contents into text segment
 - .data, .rodata says to put into data or read-only data
 - .comm symbol, size, align declares symbol and allows multiple definitions (like C but not C++, now requires -fcommon flag)
- See how function calls push arguments to stack, then pop

```
pushl $greeting # Argument to my_strlen is greeting
call my_strlen # Make the call (length now in %eax)
addl $4, %esp # Must pop greeting back off stack
```

8 / 44

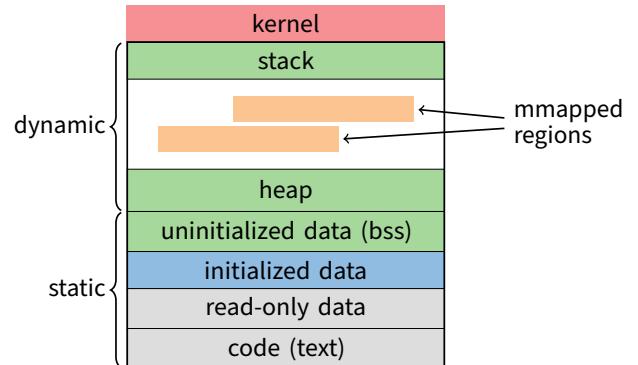

9 / 44

How is a process specified?

```
$ readelf -h hello1
ELF Header:
...
Entry point address: 0x8049030
Start of program headers: 52 (bytes into file)
Start of section headers: 14968 (bytes into file)
Number of program headers: 8
Number of section headers: 23
Section header string table index: 22
```

- Executable files are the linker/loader interface. Must tell OS:
 - What is code? What is data? Where should they live?
 - This is part of the purpose of the ELF standard
- Every ELF file starts with ELF an header
 - Specifies entry point virtual address at which to start executing
 - But how should the loader set up memory?

Recall what process memory looks like

- Address space divided into “segments”

- Text, read-only data, data, bss, heap (dynamic data), and stack
- Recall gcc told assembler in which segments to put what contents

10 / 44

11 / 44

Who builds what?

- **Heap: allocated and laid out at runtime by malloc**
 - Namespace constructed dynamically, managed by *programmer* (names stored in pointers, and organized using data structures)
 - Compiler, linker not involved other than saying where it can start
- **Stack: allocated at runtime (func. calls), layout by compiler**
 - Names are relative off of stack (or frame) pointer
 - Managed by compiler (alloc on procedure entry, free on exit)
 - Linker not involved because namespace entirely local: Compiler has enough information to build it.
- **Global data/code: allocated by compiler, layout by linker**
 - Compiler emits them and names with symbolic references
 - Linker lays them out and translates references
- **Mmapped regions: Managed by programmer or linker**
 - Some programs directly call `mmap`; dynamic linker uses it, too

12 / 44

ELF program header

```
$ readelf -l hello1
Program Headers:
Type      Offset    VirtAddr   PhysAddr  FileSiz MemSiz Flg Align
LOAD     0x001000 0x08049000 0x08049000 0x00304 0x00304 R E 0x1000
LOAD     0x002000 0x0804a000 0x0804a000 0x00158 0x00158 R 0x1000
LOAD     0x002ff8 0x0804bff8 0x0804bff8 0x0001c 0x0003c RW 0x1000
...
Section to Segment mapping:
Segment Sections...
01      ... .text ...
02      .rodata ...
03      ... .data .bss
```

- **For executables, the ELF header points to a program header**
 - Says what segments of file to map where, with what permissions
- **Segment 03 has shorter file size than memory size**
 - Only 0x1c bytes must be read into memory from file
 - Remaining 0x20 bytes constitute the .bss
- **Who creates the program header? The linker**

13 / 44

Linkers (Linkage editors)

- **Unix: ld**
 - Usually hidden behind compiler
 - Run `gcc -v hello.c` to see `ld` or invoked (may see `collect2`)
- **Three functions:**
 - Collect together all pieces of a program
 - Coalesce like segments
 - Fix addresses of code and data so the program can run
- **Result: runnable program stored in new object file**
- **Why can't compiler do this?**
- **Usually linkers don't rearrange segments, but can**
 - E.g., re-order instructions for fewer cache misses; remove routines that are never called from `a.out`

14 / 44

Linkers (Linkage editors)

- **Unix: ld**
 - Usually hidden behind compiler
 - Run `gcc -v hello.c` to see `ld` or invoked (may see `collect2`)
- **Three functions:**
 - Collect together all pieces of a program
 - Coalesce like segments
 - Fix addresses of code and data so the program can run
- **Result: runnable program stored in new object file**
- **Why can't compiler do this?**
 - Limited world view: sees one file, rather than all files
- **Usually linkers don't rearrange segments, but can**
 - E.g., re-order instructions for fewer cache misses; remove routines that are never called from `a.out`

14 / 44

Simple linker: two passes needed

- **Pass 1:**
 - Coalesce like segments; arrange in non-overlapping memory
 - Read files' symbol tables, construct global symbol table with entry for every symbol used or defined
 - Compute virtual address of each segment (at start+offset)
- **Pass 2:**
 - Patch references using file and global symbol table
 - Emit result
- **Symbol table: information about program kept while linker running**
 - Segments: name, size, old location, new location
 - Symbols: name, input segment, offset within segment

15 / 44

Where to put emitted objects?

- **Assembler:**
 - Doesn't know where data/code should be placed in the process's address space
 - Assumes each segment starts at zero
 - Emits **symbol table** that holds the name and offset of each created object
 - Routines/variables exported by file are recorded as **global definitions**
- **Simpler perspective:**
 - Code is in a big char array
 - Data is in another big char array
 - Assembler creates (object name, index) tuple for each interesting thing
 - Linker then merges all of these arrays

```
main: 0: T
:
call my_write
:
ret
my_strlen: 60: T
:
ret
main: 0: R
my_strlen: 60: t
greeting: 0: R
```

16 / 44

Object files

```
$ objdump -Sr hello2.o
```

```
...
48: 50          push  %eax
49: 68 00 00 00 00  push $0x0
                   4a: R_386_32  greeting
4e: 6a 01          push $0x1
50: e8 fc ff ff ff  call  51 <main+0x2a>
                   51: R_386_PC32 my_write
55: 83 c4 10          add   $0x10,%esp
```

- Let's create two-file program hello2 with my_write in separate file
 - Compiler and assembler can't possibly know final addresses
- Notice push uses 0 as address of greeting
- And call uses -4 as address of my_write—why?

17 / 44

Object files

```
$ objdump -Sr hello2.o
```

```
...
48: 50          push  %eax
49: 68 00 00 00 00  push $0x0
                   4a: R_386_32  greeting
4e: 6a 01          push $0x1
50: e8 fc ff ff ff  call  51 <main+0x2a>
                   51: R_386_PC32 my_write
55: 83 c4 10          add   $0x10,%esp
```

- Let's create two-file program hello2 with my_write in separate file
 - Compiler and assembler can't possibly know final addresses
- Notice push uses 0 as address of greeting
- And call uses -4 as address of my_write—why?
 - Target (sitting at offset 51 in text) encoded relative to next instruction (add at offset 55)

17 / 44

Where is everything?

- How to call procedures or reference variables?
 - E.g., call to my_write needs a target addr
 - Assembler uses 0 or PC (%eip) for address
 - Emits an external reference telling the linker the instruction's offset and the symbol it needs to be patched with

0	main:
	:
49	pushl \$0x0
4e	pushl \$0x1
50	call -4
	:
	main: 0: T
	my_strlen: 40: t
	greeting: 4a
	my_write: 51

- At link time the linker patches every reference

18 / 44

Relocations

```
$ readelf -r hello2.o
```

```
:
Offset      Info      Type          Sym. Value  Sym. Name
00000039  00000801 R_386_32    00000000  greeting
0000004a  00000801 R_386_32    00000000  greeting
00000051  00000a02 R_386_PC32 00000000  my_write
:
```

- Object file stores list of required relocations

- R_386_32 says add symbol value to value already in file (often 0)
- R_386_PC32 says add difference between symbol value and patch location to value already in file (often -4 for call)
- Info encodes type and index of symbol value to use for patch

19 / 44

ELF sections

```
$ readelf -S hello2.o
```

[Nr]	Name	Type	Addr	Off	Size	ES	Flg	Lk	Inf	Al
[0]		NULL	00000000	000000	000000	00		0	0	0
[1]	.text	PROGBITS	00000000	000034	0000a4	00	AX	0	0	1
[2]	.rel.text	REL	00000000	0005f8	000018	08	I	20	1	4
[3]	.data	PROGBITS	00000000	0000d8	000000	00	WA	0	0	1
[4]	.bss	NOBITS	00000000	0000d8	000000	00	WA	0	0	1
[5]	.rodata	PROGBITS	00000000	0000d8	00000d	00	A	0	0	4
:										
[20]	.symtab	SYMTAB	00000000	0004f0	0000d0	10		21	9	4
[21]	.strtab	STRTAB	00000000	0005c0	000038	00		0	0	1

- Memory segments have corresponding PROGBITS file segments
- But relocations and symbol tables reside in segments, too
- Segments can be arrays of fixed-size data structures
 - So strings referenced as offsets into special string segments
- Remember ELF header had section header string table index
 - That's so you can interpret names in section header

20 / 44

Symbol table

```
$ readelf -s hello2.o
```

Num:	Value	Size	Type	Bind	Vis	Ndx	Name
:							
3:	00000000	39	FUNC	LOCAL	DEFAULT	1	my_strlen
:							
9:	00000000	13	OBJECT	GLOBAL	DEFAULT	5	greeting
10:	00000027	62	FUNC	GLOBAL	DEFAULT	1	main
11:	00000000	0	NOTYPE	GLOBAL	DEFAULT	UND	my_write
:							

- Lists all global, exported symbols

- Sometimes local ones, too, for debugging (e.g., my_strlen)

- Each symbol has an offset in a particular section number

- On previous slide, 1 = .text, 5 = .rodata
- Special undefined section 0 means need symbol from other file

21 / 44

How to lay out emitted objects?

- At link time, linker first:

- Coalesces all like segments (e.g., all .text, .rodata) from all files
- Determines the size of each segment and the resulting address to place each object at
- Stores all global definitions in a global symbol table that maps the definition to its final virtual address

- Then in a second phase:

- Ensure each symbol has exactly 1 definition (except weak symbols, when compiling with -fcommon)
- For each relocation:
 - ▷ Look up referenced symbol's virtual address in symbol table
 - ▷ Fix reference to reflect address of referenced symbol

22 / 44

What is a library?

- A static library is just a collection of .o files
- Bind them together with ar program, much like tar
 - E.g., ar cr libmylib.a obj1.o obj2.o obj3.o
 - On many OSes, run ranlib libmylib.a (to build index)
- You can also list (t) and extract (x) files
 - E.g., try: ar tv /usr/lib/libc.a
- When linking a .a (archive) file, linker only pulls in needed files
 - Ensures resulting executable can be smaller than big library
- readelf will operate on every archive member (unweildy)
 - But often convenient to disassemble with objdump -d /usr/lib/libc.a

23 / 44

Examining programs with nm

```
int uninitialized;
int initialized = 1;
const int constant = 2;
int main ()
{
    return 0;
}
```

\$ nm a.out
 ...
 VA symbol type
 0400400 T _start
 04005bc R constant
 0601008 W data_start
 0601020 D initialized
 04004b8 T main
 0601028 B uninitialized

- If don't need full readelf, can use nm (nm -D on shared objects)
 - Handy -o flag prints file, useful with grep
- R means read-only data (.rodata in elf)
 - Note constant VA on same page as main
 - Share pages of read-only data just like text
- B means uninitialized data in "BSS"
- Lower-case letters correspond to local symbols (static in C)

24 / 44

Examining sections with objdump

Note Load mem addr. and File off have same page alignment for easy mmaping					
				File off	Algn
\$ objdump -h a.out	a.out:	file format elf64-x86-64			
	Sections:				
Idx	Name	Size	VMA	LMA	
..	.text	000001a8	00400400	00400400	2**4
..	.rodata	00000008	004005b8	004005b8	2**2
..	.ctors	00000010	00600e18	00600e18	2**3
..	.data	0000001c	00601008	00601008	2**3
..	.bss	0000000c	00601024	00601024	2**2
..					

CONTENTS, ALLOC, LOAD, READONLY, CODE
 CONTENTS, ALLOC, LOAD, READONLY, DATA
 CONTENTS, ALLOC, LOAD, DATA
 CONTENTS, ALLOC, LOAD, DATA
 ALLOC No contents in file

- Another portable alternative to readelf

25 / 44

Name mangling

```
// C++
int foo (int a)
{
    return 0;
}

int foo (int a, int b)
{
    return 0;
}
```

% nm overload.o
 0000000 T _Z3fooi
 000000e T _Z3fooii
 U __gxx_personality_v0
 Demangle names
 % nm overload.o | c++filt
 0000000 T foo(int)
 000000e T foo(int, int)
 U __gxx_personality_v0

- C++ can have many functions with the same name
- Compiler therefore mangles symbols
 - Makes a unique name for each function
 - Also used for methods/namespaces (obj::fn), template instantiations, & special functions such as operator new

26 / 44

Initialization and destruction

```
// C++
int a_foo_exists;
struct foo_t {
    foo_t () {
        a_foo_exists = 1;
    }
};

foo_t foo;
```

```
% cc -S -o- ctor.C | c++filt
...
.text
.align 2
__static_initialization_and_destruction_0(int, int):
...
    call    foo_t::foo_t()
```

- Initializers run before main
 - Mechanism is platform-specific
- Example implementation:
 - Compiler emits static function in each file running initializers
 - Wrap linker with collect2 program that generates __main function calling all such functions
 - Compiler inserts call to __main when compiling real main

27 / 44

Other information in executables

```
// C++
struct foo_t {
    ~foo_t() {/*...*/}
    except() { throw 0; }
};

void fn () {
    foo_t foo;
    foo.except();
    /* ... */
}
```

- Throwing exceptions destroys automatic variables
- During exception, must find
 - All such variables with non-trivial destructors
 - In all procedures' call frames until exception caught
- Record info in special sections
- Executables can include debug info (compile w. -g)
 - What source line does each binary instruction correspond to?

28 / 44

Dynamic (runtime) linking (hello3.c)

```
#include <dlfcn.h>
int main(int argc, char **argv, char **envp)
{
    size_t (*my_strlen)(const char *p);
    int (*my_write)(int, const void *, size_t);
    void *handle = dlopen("dest/libmy.so", RTLD_LAZY);
    if (!handle)
        || !(my_strlen = dlsym(handle, "my_strlen"))
        || !(my_write = dlsym(handle, "my_write")))
        return 1;
    return my_write(1, greeting, my_strlen(greeting)) < 0;
}
```

- Link time isn't special, can link at runtime too
 - Get code (e.g., plugins) not available when program compiled
- Issues:
 - How can behavior differ compared to static linking?
 - Where to get unresolved symbols (e.g., my_write) from?
 - How does my_write know its own addresses (e.g., for my_errno)?

29 / 44

Dynamic linking (continued)

- How can behavior differ compared to static linking?
 - Runtime failure (can't find file, doesn't contain symbols)
 - No type checking of functions, variables
- Where to get unresolved symbols (e.g., my_write) from?
 - dlsym must parse ELF file to find symbols
- How does my_write know its own addresses?

```
$ readelf -r dest/libmy.so

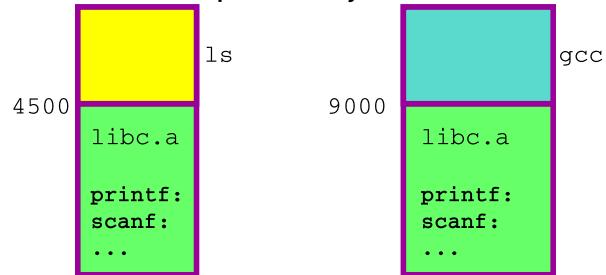

Relocation section '.rel.dyn' at offset 0x20c contains 1 entry:
Offset     Info      Type            Sym.Value  Sym. Name
00003ffc  00000106 R_386_GLOB_DAT    0000400c  my_errno
```

- dlopen, too, must parse ELF to patch relocations

30 / 44

Static shared libraries

- Observation: everyone links in standard libraries (libc.a.), these libs consume space in every executable.

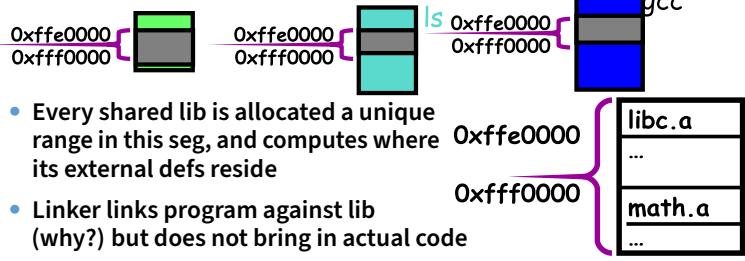

- Insight: we can have a single copy on disk if we don't actually include libc code in executable

31 / 44

Static shared libraries

- Define a “shared library segment” at same address in every program’s address space

- Every shared lib is allocated a unique range in this seg, and computes where its external defs reside
- Linker links program against lib (why?) but does not bring in actual code
- Loader marks shared lib region as unreadable
- When process calls lib code, seg faults: embedded linker brings in lib code from known place & maps it in.
- Now different running programs can share code!

32 / 44

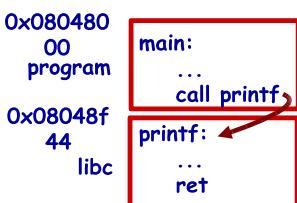

Dynamic shared libraries

- Static shared libraries require system-wide pre-allocation of address space
 - Clumsy, inconvenient
 - What if a library gets too big for its space? (fragmentation)
 - Can't upgrade libraries w/o relinking applications
 - Can space ever be reused?
- Solution: Dynamic shared libraries
 - Combine shared library and dynamic linking ideas
 - Any library can be loaded at any VA, chosen at runtime
- New problem: Linker won't know what names are valid
 - Solution: stub library
- New problem: How to call functions whose position varies?
 - Solution: next page...

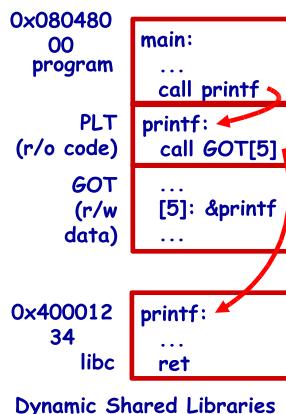

33 / 44

Position-independent code

- Code must be able to run anywhere in virtual mem
- Runtime linking would prevent code sharing, so...
- Add a level of indirection!

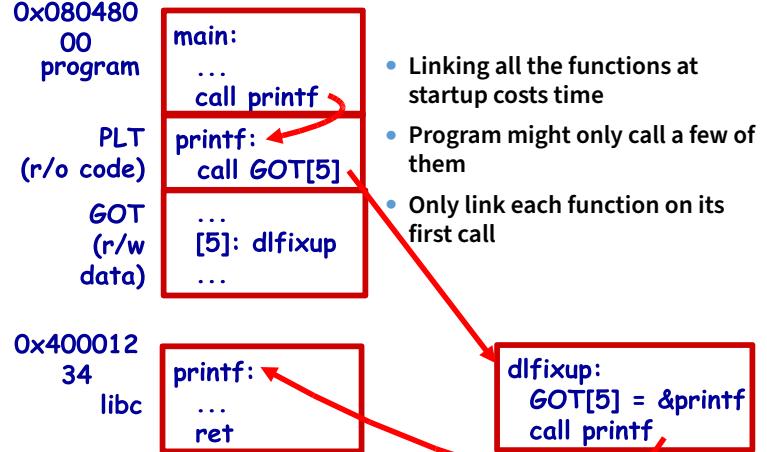

Static Libraries

Dynamic Shared Libraries

34 / 44

Lazy dynamic linking

35 / 44

Dynamic linking with ELF

- Every dynamically linked executable needs an *interpreter*
 - Embedded as string in special .interp section
 - readelf -p .interp /bin/ls → /lib64/ld-linux-x86-64.so.2
 - So all the kernel has to do is run ld-linux
- dlfixup uses hash table to find symbols when needed
- Hash table lookups can be quite expensive [Drepper]
 - E.g., big programs like OpenOffice very slow to start
 - Solution 1: Use a better hash function
 - linux added .gnu.hash section, later removed .hash sections
 - Solution 2: Export fewer symbols. Now fashionable to use:
 - gcc -fvisibility=hidden (keep symbols local to DSO)
 - #pragma GCC visibility push(hidden)/visibility pop
 - __attribute__((visibility("default"))), (override for a symbol)

36 / 44

Dynamic shared library example: hello4

```
$ objdump -Sr hello4
:
08049030 <my_write@plt>:
 8049030: ff 25 0c c0 04 08    jmp   *0x804c00c
 8049036: 68 00 00 00 00        push  $0x0
 804903b: e9 e0 ff ff ff        jmp   8049020 <.plt>

08049040 <my_strlen@plt>:
 8049040: ff 25 10 c0 04 08    jmp   *0x804c010
 8049046: 68 08 00 00 00        push  $0x8
 804904b: e9 d0 ff ff ff        jmp   8049020 <.plt>
  :
 804917a: 68 08 a0 04 08        push  $0x804a008
 804917f: e8 bc fe ff ff        call   8049040 <my_strlen@plt>
```

- 0x804c00c and 0x804c010 initially point to next instruction
 - Calls dlfixup with relocation index
 - dlfixup needs no relocation because jmp takes relative address

37 / 44

hello4 relocations

```
$ readelf -r hello4
Relocation section '.rel.plt' at offset 0x314 contains 2 entries:
Offset     Info      Type            Sym. Value  Sym. Name
0804c00c  00000107 R_386_JUMP_SLOT 00000000  my_write
0804c010  00000507 R_386_JUMP_SLOT 00000000  my_strlen
```

- PLT = procedure linkage table on last slide
 - Small 16 byte snippets, read-only executable code
- dlfixup Knows how to parse relocations, symbol table
 - Looks for symbols by name in hash tables of shared libraries
- my_write & my_strlen are pointers in global offset table (GOT)
 - GOT non-executable, read-write (so dlfixup can fix up)
- Note hello4 knows address of greeting, PLT, and GOT
 - How does a shared object (libmy.so) find these?
 - PLT is okay because calls are relative
 - In PIC, compiler reserves one register %ebx for GOT address

38 / 44

hello4 shared object contents

mywrite.c

```
int my_errno;
int my_write(int fd, const void *buf, size_t len) {
    int ret;
    asm volatile /* ... */;
    if (ret < 0) {
        my_errno = -ret;
        return -1;
    }
    return ret;
}
```

mywrite.s

```
negl %eax
movl %eax, %edx
movl my_errno@GOT(%ebx), %eax
movl %edx, (%eax)
```

mywrite-pic.s

```
negl %eax
movl %eax, %edx
movl my_errno@GOT(%ebx), %eax
movl %edx, (%eax)
```

39 / 44

How does %ebx get set?

mywrite-pic.s

```
my_write:
    pushl %ebp
    movl %esp, %ebp
    pushl %ebx
    subl $16, %esp
    call __x86.get_pc_thunk.bx
    addl ${_GLOBAL_OFFSET_TABLE_}, %ebx
    :
__x86.get_pc_thunk.bx:
    movl (%esp), %ebx
    ret
```

```
$ readelf -r .libs/mywrite.o
Offset Info Type Sym.Value Sym. Name
00000008 00000a02 R_386_PC32 00000000 __x86.get_pc_thunk.bx
0000000e 00000b0a R_386_GOTPC 00000000 _GLOBAL_OFFSET_TABLE_
00000036 0000082b R_386_GOT32X 00000000 my_errno
```

40 / 44

Linking and security

```
void fn ()
{
    char buf[80];
    gets (buf);
    /* ... */
}
```

1. Attacker puts code in buf
 - Overwrites return address to jump to code
 2. Attacker puts shell command above buf
 - Overwrites return address so function "returns" to system function in libc
- People try to address problem with linker
 - W^X: No memory both writable and executable
 - Prevents 1 but not 2, must be disabled for jits
 - Address space randomization
 - Makes attack #2 a little harder, not impossible
 - Leads to position-independent executable, compiled -fPIE and linked -pie—like PIC for executables
 - Also address with compiler (stack protector, CFI)

41 / 44

Linking Summary

- Compiler/Assembler: 1 object file for each source file
 - Problem: incomplete world view
 - Where to put variables and code? How to refer to them?
 - Names definitions symbolically ("printf"), refers to routines/variable by symbolic name
- Linker: combines all object files into 1 executable file
 - Big lever: global view of everything. Decides where everything lives, finds all references and updates them
 - Important interface with OS: what is code, what is data, where is start point?
- OS loader reads object files into memory:
 - Allows optimizations across trust boundaries (share code)
 - Provides interface for process to allocate memory (sbrk)

42 / 44

Code = data, data = code

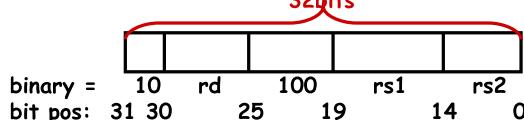

- No inherent difference between code and data
 - Code is just something that can be run through a CPU without causing an "illegal instruction fault"
 - Can be written/read at runtime just like data "dynamically generated code"
- Why? Speed (usually)
 - Big use: eliminate interpretation overhead. Gives 10-100x performance improvement
 - Example: Just-in-time Javascript compiler, or qemu vs. bochs
 - In general: optimizations thrive on information. More information at runtime.
- The big tradeoff:
 - Total runtime = code gen cost + cost of running code

43 / 44

How?

- Determine binary encoding of desired instructions

SPARC: sub instruction
symbolic = "sub rdst, rsrc1, rsrc2"

- Write these integer values into a memory buffer

```
unsigned code[1024], *cp = &code[0];
/* sub %g5, %g4, %g3 */
*cp++ = (2<<30) | (5<<25) | (4<<19) |(4<<14) | 3;
...

```
- Use mprotect to disable W^X
- Jump to the address of the buffer: ((int (*)())code)();

44 / 44

```

hello/hello1.c      Sun Jan 08 16:03:41 2023      1
/* (from glibc sysdeps/unix/sysv/linux/i386/sysdep.h)
   https://sourceware.org/git/?p=glibc.git;a=blob;f=sysdeps/unix/sysv/linux/i386/sysdep
.h

Linux takes system call arguments in registers:

    syscall number  %eax          call-clobbered
    arg 1           %ebx          call-saved
    arg 2           %ecx          call-clobbered
    arg 3           %edx          call-clobbered
    arg 4           %esi          call-saved
    arg 5           %edi          call-saved
    arg 6           %ebp          call-saved
*/
