Overview of previous and current lectures

- Locks create serial code
  - Serial code gets no speedup from multiprocessors
- Test-and-set spinlock has additional disadvantages
  - Lots of traffic over memory bus
  - Not fair on NUMA machines
- Idea 1: Avoid spinlocks
  - We saw lock-free algorithms last lecture
  - Introduced RCU last time, dive deeper today
- Idea 2: Design better spinlocks
  - Less memory traffic, better fairness
- Idea 3: Hardware turns coarse- into fine-grained locks!
  - While also reducing memory traffic for lock in common case

Outline

1. RCU
2. Improving spinlock performance
3. Kernel interface for sleeping locks
4. Deadlock
5. Transactions
6. Scalable interface design

Read-copy update [McKenney]

- Some data is read way more often than written
  - Routing tables consulted for each forwarded packet
  - Data maps in system with 100+ disks (updated on disk failure)
- Optimize for the common case of reading without lock
  - Have global variable: _Atomic(routing_table *) rt;
  - Use it with no lock
    
    ```c
    #define RELAXED(var) \
    atomic_load_explicit(&var, memory_order_relaxed)
    
    route = lookup(RELAXED(rt), destination);
    ```

- Update by making copy, swapping pointer
  
  ```c
  routing_table *newrt = copy_routing_table(rt);
  update_routing_table(newrt);
  atomic_store_explicit(&rt, newrt, memory_order_release);
  ```

Preemptible kernels

- Recall kernel process context from lecture 1
  - When CPU in kernel mode but executing on behalf of a process (e.g., might be in system call or page fault handler)
  - As opposed to interrupt handlers or context switch code
- A preemptible kernel can preempt process context code
  - Take a CPU core away from kernel process context code between any two instructions
  - Give the same CPU core to kernel code for a different process
- Don't confuse with:
  - Interrupt handlers can always preempt process context code
  - Preemptive threads (always have for multicore)
  - Process context code running concurrently on other CPU cores
- Sometimes want or need to disable preemption
  - E.g., before acquiring spinlock also used by interrupt handler
  - In code that must not be migrated between CPUs

Is RCU really safe?

- Consider the use of global rt with no fences:
  ```c
  lookup(RELAXED(rt), route);
  ```
- Could a CPU read new pointer but then old contents of *rt?
- Yes on alpha, No on all other existing architectures
- We are saved by dependency ordering in hardware
  - Instruction B depends on A if B uses result of A
  - Non-alpha CPUs won’t re-order dependent instructions
  - If writer uses release fence, safe to load pointer then just use it
- This is the point of memory_order_consume
  - Should be equivalent to acquire barrier on alpha
  - But should compile to nothing (be free) on other machines
  - But hard to get semantics right (temporarily deprecated in C++)

Garbage collection

- When can you free memory of old routing table?
  - When you are guaranteed no one is using it—how to determine?
- Definitions:
  - temporary variable – short-used (e.g., local) variable
  - permanent variable – long lived data (e.g., global rt pointer)
  - quiescent state – when all a thread’s temporary variables dead
  - quiescent period – time during which every thread has been in quiescent state at least once
- Free old copy of updated data after quiescent period
  - How to determine when quiescent period has gone by?
  - E.g., keep count of syscalls/context switches on each CPU
- Restrictions:
  - Can’t hold a pointer across context switch or user mode
    (Never copy rt into another permanent variable)
  - Must disable preemption while consuming RCU data structure

6. Scalable interface design

---

**MCS Acquire**

acquire (lock *L, qnode *I) {
I->next = NULL;
qnode *predecessor = I;
XCHG (*L, predecessor);
if (predecessor != NULL) {
  I->locked = true;
predecessor->next = I;
  while (I->locked)
  }
}

• If unlocked, *L is NULL
• If locked, no waiters, *L is owner’s qnode
• If waiters, *I is tail of waiter list:

![MCS Acquire Diagram](image)

---

**MCS Acquire**

acquire (lock *L, qnode *I) {
I->next = NULL;
qnode *predecessor = I;
XCHG (*L, predecessor);
if (predecessor != NULL) {
  I->locked = true;
predecessor->next = I;
  while (I->locked)
  }
}

• If unlocked, *L is NULL
• If locked, no waiters, *L is owner’s qnode
• If waiters, *I is tail of waiter list:

![MCS Acquire Diagram](image)

---

**Useful macros**

- Atomic compare and swap: CAS (mem, old, new)
  - In C11: atomic_compare_exchange_strong
  - On x86: cmpxchg instruction provides this (with lock prefix)
  - If *mem == old, then swap *mem=new and return true, else false
- Atomic swap: XCHG (mem, new)
  - C11 atomic_exchange, can implement with xchg on x86
  - Atomically exchanges *mem=new
- Atomic fetch and add: FADD (mem, val)
  - C11 atomic_fetch_add, can implement with lock add on x86
  - Atomically sets *mem += val and returns old value of *mem
- Atomic fetch and subtract: FSUB (mem, val)
  - C11 atomic_fetch_sub, can implement with lock sub on x86
  - Atomically sets *mem -= val and returns old value of *mem
- Note: atomics return previous value (like x++, not ++x)
- All behave like sequentially consistent fences, too
  - Unlike _explicit versions, which take a memory_order argument

---

**MCS lock**

- Idea 2: Build a better spinlock
- Lock designed by Mellor-Crummey and Scott
  - Goal: reduce bus traffic on cc machines, improve fairness
- Each CPU has a qnode structure in local memory

typedef struct qnode {
  _Atomic (struct qnode *) next;
  atomic_bool locked;
} qnode;

  - Local can mean local memory in NUMA machine
  - Or just its own cache line that gets cached in exclusive mode
- A lock is a qnode pointer: typedef _Atomic (qnode *) lock;
  - Construct list of CPUs holding or waiting for lock
  - lock itself points to tail of list
- While waiting, spin on your local locked flag

![MCS lock Diagram](image)
MCS Acquire

acquire (lock *L, qnode *I) {
    I->next = NULL;
    qnode *predecessor = I;
    XCHG (*L, predecessor);
    if (predecessor != NULL) {
        I->locked = true;
        predecessor->next = I;
        while (I->locked);
    }
}

- If unlocked, L is NULL
- If locked, no waiters, L is owner's qnode
- If waiters, *L is tail of waiter list:

MCS Release with CAS

release (lock *L, qnode *I) {
    if (!I->next)
        if (CAS (*L, I, NULL))
            return;
    while (!I->next);
    I->next->locked = false;
}

- If I->next NULL and *L == I
  - No one else is waiting for lock, OK to set *L = NULL

- If I->next non-NULL
  - I->next oldest waiter, wake up with I->next->locked = false

MCS Release w/o CAS

- What to do if no atomic CAS (consensus number ∞), but do have XCHG (consensus number 2)?
- Be optimistic—read *L with two XCHGS:
  1. Atomically swap NULL into *L
     - If old value of *L was I, no waiters and we are done
  2. Atomically swap old *L value back into *L
     - If *L unchanged, same effect as CAS
- Otherwise, we have to clean up the mess
  - Some "userper" attempted to acquire lock between 1 and 2
  - Because *L was NULL, the userper succeeded
    (May be followed by zero or more waiters)
  - Stick old list of waiters on to end of new last waiter
    (Sacrifice small amount of fairness, but still safe)
Outline

1. RCU
2. Improving spinlock performance
3. Kernel interface for sleeping locks
4. Deadlock
5. Transactions
6. Scalable interface design

Kernel support for sleeping locks

- Sleeping locks must interact with scheduler
  - For processes or kernel threads, must go into kernel (expensive)
  - Common case is you can acquire lock—how to optimize?
- Idea: never enter kernel for uncontested lock

```
struct lock {
    atomic_flag busy;
    _Atomic (thread *) waiters; /* wait-free stack/queue */
};
void acquire (lock *lk) {
    while (atomic_flag_test_and_set (&lk->busy)) { /* 1 */
        atomic_push (&lk->waiters, self); /* 2 */
        sleep ();
    }
}
void release (lock *lk) {
    atomic_flag_clear(&lk->busy);
    wakeup (atomic_pop (&lk->waiters));
}
```

Race condition

- Unfortunately, previous slide not safe
  - What happens if release called between lines 1 and 2?
  - wakeup called on NULL, so acquire blocks
- futex abstraction solves the problem [Franke]
  - Ask kernel to sleep only if memory location hasn’t changed
- void futex (int *uaddr, FUTEX_WAIT, int val...);
  - Go to sleep only if *uaddr == val
  - Extra arguments allow timeouts, etc.
- void futex (int *uaddr, FUTEX_WAKE, int val...);
  - Wake up at most val threads sleeping on uaddr
- uaddr is translated down to offset in VM object
  - So works on memory mapped file at different virtual addresses in different processes

Futex example

```
struct lock {
    atomic_flag busy;
};
void acquire (lock *lk) {
    while (atomic_flag_test_and_set (&lk->busy))
        futex(&lk->busy, FUTEX_WAIT, 1);
}
void release (lock *lk) {
    if (FSUB(&lk->busy, 1) != 1) {
        lk->busy = 0;
        futex((int*) &lk->busy, FUTEX_WAKE, 1);
    }
}
```

- What’s suboptimal about this code?
  - release requires a system call (expensive) even with no contention
- See [Drepper] for these examples and a good discussion

Futex example, second attempt

```
static_assert (ATOMIC_INT_LOCK_FREE >= 2);
struct lock {
    atomic_flag busy;
};
void acquire (lock *lk) {
    while (atomic_flag_test_and_set (&lk->busy))
        futex((int*) &lk->busy, FUTEX_WAIT, 1);
}
void release (lock *lk) {
    if (FSUB(&lk->busy, 1) != 1) {
        lk->busy = 0;
        futex((int*) &lk->busy, FUTEX_WAKE, 1);
    }
}
```

- Now what’s wrong with this code?
- Two threads could interleave lines 1 and 2, never sleep
- Could even overflow the counter, violate mutual exclusion
- See [Drepper] for these examples and a good discussion
Futex example, second attempt

static_assert (ATOMIC_INT_LOCK_FREE >= 2);

struct lock {
    atomic_int busy;
};

void acquire (lock *lk) {
    int c;
    while ((c = FADD(&lk->busy, 1))) /* 1 */
        futex((int*) &lk->busy, FUTEX_WAIT, c+1); /* 2 */
}

void release (lock *lk) {
    if (FSUB(&lk->busy, 1) != 1) {
        lk->busy = 0;
        futex((int*) &lk->busy, FUTEX_WAKE, 1);
    }
}

• Now what's wrong with this code?
  - Two threads could interleave lines 1 and 2, never sleep
  - Could even overflow the counter, violate mutual exclusion

Futex example, third attempt

struct lock {
    // 0=unlocked, 1=locked no waiters, 2=locked+waiters
    atomic_int state;
};

void acquire (lock *lk) {
    int c = 1;
    if (!CAS (&lk->state, 0, c)) {
        XCHG (&lk->state, c = 2);
        while (c != 0) {
            futex ((int *) &lk->state, FUTEX_WAIT, 2);
            XCHG (&lk->state, c = 2);
        }
    }
}

void release (lock *lk) {
    if (FSUB (&lk->state, 1) != 1) { // FSUB returns old value
        lk->state = 0;
        futex ((int *) &lk->state, FUTEX_WAKE, 1);
    }
}

Outline

1 RCU
2 Improving spinlock performance
3 Kernel interface for sleeping locks
4 Deadlock
5 Transactions
6 Scalable interface design

The deadlock problem

mutex_t m1, m2;

void p1 (void *ignored) {
    lock (m1);
    lock (m2);
    /* critical section */
    unlock (m2);
    unlock (m1);
}

void p2 (void *ignored) {
    lock (m2);
    lock (m1);
    /* critical section */
    unlock (m1);
    unlock (m2);
}

• This program can cease to make progress – how?
• Can you have deadlock w/o mutexes?

More deadlocks

• Same problem with condition variables
  - Suppose resource 1 managed by c1, resource 2 by c2
  - A has 1, waits on c2; B has 2, waits on c1

• Or have combined mutex/condition variable deadlock:
  - lock (a); lock (b); while (!ready) wait (b, c);
    unlock (b); unlock (a);
  - lock (a); lock (b); ready = true; signal (c);
    unlock (b); unlock (a);

• One lesson: Dangerous to hold locks when crossing abstraction barriers!
  - I.e., lock (a) then call function that uses condition variable

Deadlocks w/o computers

• Real issue is resources & how required
• E.g., bridge only allows traffic in one direction
  - Each section of a bridge can be viewed as a resource.
  - If a deadlock occurs, it can be resolved if one car backs up (preempt resources and rollback).
  - Several cars may have to be backed up if a deadlock occurs.
  - Starvation is possible.
Deadlock conditions

1. **Limited access (mutual exclusion):**
   - Resource can only be shared with finite users

2. **No preemption:**
   - Once resource granted, cannot be taken away

3. **Multiple independent requests (hold and wait):**
   - Don’t ask all at once
     (wait for next resource while holding current one)

4. **Circularity in graph of requests**
   - All of 1–4 necessary for deadlock to occur
   - Two approaches to dealing with deadlock:
     - Pro-active: prevention
     - Reactive: detection + corrective action

Prevent by eliminating one condition

1. **Limited access (mutual exclusion):**
   - Buy more resources, split into pieces, or virtualize to make "infinite" copies
   - Threads: threads have copy of registers = no lock

2. **No preemption:**
   - Physical memory: virtualized with VM, can take physical page away and give to another process!

3. **Multiple independent requests (hold and wait):**
   - Wait on all resources at once (must know in advance)

4. **Circularity in graph of requests**
   - Single lock for entire system: (problems?)
   - Partial ordering of resources (next)

Resource-allocation graph

- View system as graph
  - Processes and Resources are nodes
  - Resource Requests and Assignments are edges

- Process:
- Resource with 4 instances:
  - \( P_i \) requesting \( R_j \):
  - \( P_i \) holding instance of \( R_j \):

Example resource allocation graph

Graph with deadlock

Is this deadlock?
Cycles and deadlock

• If graph has no cycles \(\Rightarrow\) no deadlock
• If graph contains a cycle
  - Definitely deadlock if only one instance per resource
  - Otherwise, maybe deadlock, maybe not
• Prevent deadlock with partial order on resources
  - E.g., always acquire mutex \(m_1\) before \(m_2\)
  - Usually design locking discipline for application this way

Prevention

• Determine safe states based on possible resource allocation
• Conservatively prohibits non-deadlocked states

Claim edges

• Dotted line is claim edge
  - Signifies process may request resource

Example: unsafe state

• Note cycle in graph
  - \(P_1\) might request \(R_2\) before relinquishing \(R_1\)
  - Would cause deadlock

Detecting deadlock

• Static approaches (hard)
• Dynamically, program grinds to a halt
  - Threads package can diagnose by keeping track of locks held:

Fixing & debugging deadlocks

• Reboot system / restart application
• Examine hung process with debugger
• Threads package can deduce partial order
  - For each lock acquired, order with other locks held
  - If cycle occurs, abort with error
  - Detects potential deadlocks even if they do not occur
• Or use transactions...
  - Another paradigm for handling concurrency
  - Often provided by databases, but some OSes use them
  - Vino OS used transactions to abort after failures [Seltzer]
Transactions

- A transaction $T$ is a collection of actions with
  - Atomicity – all or none of actions happen
  - Consistency – $T$ leaves data in valid state
  - Isolation – $T$'s actions all appear to happen before or after every other transaction
  - Durability – $T$'s effects will survive reboots
  - Often hear mnemonic ACID to refer to above

Transactions typically executed concurrently
- But isolation means must appear not to
- Must roll-back transactions that use others’ state
- Means you have to record all changes to undo them

When deadlock detected just abort a transaction
- Breaks the dependency cycle

Transactions

- A transaction $T$ is a collection of actions with
  - Atomicity – all or none of actions happen
  - Consistency – $T$ leaves data in valid state
  - Isolation – $T$'s actions all appear to happen before or after every other transaction
  - Durability – $T$'s effects will survive reboots
  - Often hear mnemonic ACID to refer to above

Transactions typically executed concurrently
- But isolation means must appear not to
- Must roll-back transactions that use others’ state
- Means you have to record all changes to undo them

When deadlock detected just abort a transaction
- Breaks the dependency cycle

Using transactional memory

- Idea 3: Use to get “free” fine-grained locking on a hash table
  - E.g., concurrent inserts that don’t touch same buckets are okay
  - Should read spinlock to make sure not taken (but not write) [Kim]
  - Hardware will detect there was no conflict

Can also use to poll for one of many asynchronous events
- Start transaction
- Fill cache with values to which you want to see changes
- Loop until a write causes your transaction to abort

Note: Transactions are never guaranteed to commit
- Might overflow cache, get false sharing, see weird processor issue
- Means abort path must always be able to perform transaction (e.g., you do need a lock on your hash table)

Transactional memory

- Some modern processors support transactional memory
- Transactional Synchronization Extensions (TSX) [intel§16]
  - xbegin abort_handler – begins a transaction
  - xend – commit a transaction
  - xabort $code – abort transaction with 8-bit code
  - Note: nested transactions okay (also xtest tests if in transaction)

During transaction, processor tracks accessed memory
- Keeps read-set and write-set of cache lines
- Nothing gets written back to memory during transaction
- On xend or earlier, transaction aborts if any conflicts
- Otherwise, all dirty cache lines are written back atomically

Hardware lock elision (HLE)

- Idea: make it so spinlocks rarely need to spin
  - Begin a transaction when you acquire lock
  - Other CPUs won’t see lock acquired, can also enter critical section
  - Okay not to have mutual exclusion when no memory conflicts!
  - On conflict, abort and restart without transaction, thereby visibly acquiring lock (and aborting other concurrent transactions)

Intel support:
- Use xacquire prefix before xchg1 (used for test and set)
- Use xrelease prefix before mov1 that releases lock
- Prefixes chosen to be noops on older CPUs (binary compatibility)

Hash table example:
- Use xacquire xchg1 in table-wide test-and-set spinlock
- Works correctly on older CPUs (with coarse-grained lock)
- Allows safe concurrent accesses on newer CPUs!

Outline

1 RCU
2 Improving spinlock performance
3 Kernel interface for sleeping locks
4 Deadlock
5 Transactions
6 Scalable interface design

Hash table example:
- Use xacquire xchg1 in table-wide test-and-set spinlock
- Works correctly on older CPUs (with coarse-grained lock)
- Allows safe concurrent accesses on newer CPUs!
Scalable interfaces

- Not all interfaces can scale
- How to tell which can and which can’t?
- Scalable Commutativity Rule: “Whenever interface operations commute, they can be implemented in a way that scales” [Clements]

Are fork(), execve() broadly commutative?

pid_t pid = fork();
if (!pid)
    execlp("bash", "bash", NULL);

- No, fork() doesn’t commute with memory writes, many file descriptor operations, and all address space operations
  - E.g., close(fd); fork(); vs. fork(); close(fd);
- execve() often follows fork() and undoes most of fork()'s sub operations
- posix_spawn(), which combines fork() and execve() into a single operation, is broadly commutative
  - But obviously more complex, less flexible
  - Maybe Microsoft will have the last laugh?

Is open() broadly commutative?

int fd1 = open("foo", O_RDONLY);
int fd2 = open("bar", O_RDONLY);

- Actually open() does not broadly commute!
- Does not commute with any system call (including itself) that creates a file descriptor
- Why? POSIX requires new descriptors to be assigned the lowest available integer
- If we fixed this, open() would commute, as long as it is not creating a file in the same directory as another operation
